The Massachusetts Medical Society

*May it flourish & prosper, May it continue to im-
prove the Art for which it ^{was} instituted, to the utmost
of its Wishes, and be the Means under Providence,
of alleviating the Pains & Evils of Life, & promoting
the Happiness of Society by suppressing Quackery, &
rendering the Business of the Profession as perfect as
the Nature of Things, admits*

*and may each Individual of the Society, and
every other Gentleman here present, enjoy Health
and Prosperity, In the pleasing consciousness that
He has contributed somewhat to the advancement &
improvement of the public Welfare*

DR. EDWARD A. HOLYOKE,

FIRST PRESIDENT OF THE MASSACHUSETTS MEDICAL SOCIETY.

W. B. K. Sketched the above portrait of him at the public dinner given in his honor by the Faculty
of Boston School, and various, on his Centennial Birthday, August 13, 1823.

INDEX TO VOLUME CIV.

- Abbot, S. L., and Fitz, R. H.** A case of hydrophobia of doubtful origin, 147.
- Albee.** Anchylosis of bones of hand, 135.
- Allen, C. A.** Popliteal aneurism following amputation, 435.
- Allen, D. P.** Letters from Leipzig, 500, 525.
- Anatomy.** European and American anatomy acts compared, Hartwell, E. M., 27, 56; recent progress in anatomy, Dwight, T., 241; a novel method of teaching clinical anatomy, 357; frozen sections of heads, Dwight, T., 468.
- Appleton, W. W.** Letter to Dr. E. A. Holyoke, 533.
- Ayer, J.** Measles, 179.
- Ayer, J. B.** Alcoholic mania in connection with acute disease, 180.
- Baker, W. H.** Recent progress in gynecology, 29; gynecology in New York and Brooklyn, 127.
- Baltimore.** The computation of death-rates as illustrated by Baltimore, 257.
- Bancroft, C. P.** Aphasia complicated with insanity, 483.
- Beach, H. H. A.** Recent progress in surgery, 585.
- Beard, G. M.** Mesmeric trance, 255; the eye in trance and other symptoms, 334.
- Bibliography.** Association of Medical Officers of American Institutions for Idiote and Feeble-Minded Persons, Proceedings, 251; Beale, L. S., on Slight Aliments, their Nature and Treatment, 38; Beal, G. M., and Rockwell, A. D., Practical Treatise on the Medical and Surgical Uses of Electricity, 309; Brown, F. H. Indexes to Medical Literature, 318; Buck, A. H., Diagnosis and Treatment of Ear Diseases, 115; Chapin, C. V., The Sympathetic Nerve, its Relations to Disease, 423; Clowes, F., An Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis, 232; Coles, A., The Microcosm and other Poems, 254; Da Costa, J. M., Medical Diagnosis, with Special Reference to Practical Medicine, 232; Day, W. H., Diseases of Children, 522; Dunglison, R. J., A New School Physiology, 400; Dubrincz, L. A., A Practical Treatise on Diseases of the Skin, 205; Edwards, J. F., Constipation plainly Treated and Relieved without the Use of Drugs, 304; Ellis, E., What every Mother should Know, 435; Flint A., Treatise on the Principles and Practice of Medicine, 231; Flint, A., Jr., A Text-Book of Human Physiology, 332; Flower, W. H., Diagrams of the Nerves of the Human Body, 279; Fothergill, G. M., Food for the Invalid, 256; Fothergill, J. M., Students' Aid Series, Aids to Diagnosis, Semiology, 422; Fourrier on Syphilis and Marriage, 256; Fox, G. H., Photographic Illustrations of Cutaneous Syphilis, 38, 181, 422; Gangsee, A., A Text-Book of the Physiological Chemistry of the Animal Body, 153; Garner, M. P., Dictionnaire Annuel de Progrès des Sciences et Institutions Médicales, 333; Garretson, J. E., A System of Oral Surgery, 447; Gibbs, H., Practical Histology and Pathology, 87; Gross, S. D., John Hunter and his Pupils, 159; Hazen, R., A Guide to the Clinical Examination of Patients and the Diagnosis of Disease, 424; Hall, F. de H., Differential Diagnosis, 184; Hamilton, F. H., A Practical Treatise on Fractures and Dislocations, 563; Hammond, W. A., On Certain Conditions of Nervous Derangement, Somnambulism, Hypnotism, Hysteria, Hysteroid Affections, etc., 304; Hammond, W. A., and Morton, W. J., Neurological Contributions, 206; Hewitt, G., The Pathology, Diagnosis, and Treatment of Diseases of Women, including the Diagnosis of Pregnancy, 149; Index Catalogue, 187; Index Medicus, 43; Jacobi, A., A Treatise on Diphtheria, 183; Jacobi, M. P., and White, V. A., on the Use of the Cold Pack followed by Massage in the Treatment of Anæmia, 208; Kirkbride, T. S., On the Construction, Organization, and General Arrangements of Hospitals for the Insane, with some Remarks on Insanity and its Treatment, 15; Klein and Smith's Atlas of Histology, Part XIII., 184; Landis, H. G., How to Use the Forceps, 111; Lane, J. R., Lectures on Syphilis, 322; Lee, J. G., Hand-Book for Coroners, 255; Legg, J. W., On the Bile, Jaundice, and Bilious Diseases, 333; Martin, H. N., The Human Body, 460; Mitchell, S. W., Lectures on Diseases of the Nervous System, especially in Women, 521; Oldberg, O., The Metric System in Medicine, 423; Otis, F. N., Clinical Lectures on the Physiological Pathology and Treatment of Syphilis, 182; Pfaff, H. G., Treatise on the Materia Medica and Therapeutics of the Skin, 400; Ranney, A. L., Anatomical Plates arranged as a Companion Volume for The Essentials of Anatomy, 448; Report of the Commissioner of Education for 1878, 16; Roosa, D. B. St. J., Ophthalmic and Otic Memoranda, 39; Roosa, D. B. St. J., and Ely, E. T., Ophthalmic and Otic Contributions, 140; Savage, H., The Surgery, Surgical Pathology, and Surgical Anatomy of the Female Pelvic Organs, 333; Seiler, C., Compendium of Microscopical Technology, 268; Smith, A., Ringworm, its Diagnosis and Treatment, 111; Smythe, G. C., Medical Heresies historically Considered, 448; Stevens, C. W., Revelations of a Boston Physician, Stowell, C. H., 208; The Student's Manual of Histology, for the Use of Students, Practitioners, and Microscopists, 424; Taylor, A. S., A Manual of Medical Jurisprudence, 3; The Sanitary Care and Treatment of Children and their Diseases, 615; Thomas, T. G., A Practical Treatise on the Diseases of Women, 333; Thompson, H., Clinical Records and Cases, with Commentaries, 39; Warner, F., The Student's Guide to Medical Case-Taking, 424; Moir, H. E., A Manual of the Practice of Medicine, designed for the Use of Students and the General Practitioner, 424; Warren, J. C., Colic and Adipose, 203; Wells, S., Note-Book for Cases of Ovarian and other Abdominal Tumors, 522; Witkowski, G. J., A Pictorial Manual, or Movable Atlas of the Human Body, showing the Position of the Internal Organs by means of Superposed Colored Plates, 111; Wood, H. C., Fever, a Study in Morbid and Normal Physiology, 375.
- Billings, J. S.** Some of the results of the tenth census as regards mortality statistics, 517.
- Bibliography.** Alden, E., 116; Buckland, F., 212; Caro, S., 476; Cowling, H. O., 378, 492; "Eliot, George," 149; Field, C. C., 544; Ford, G., 91; Garland, G. W., 480; Hodge, H. L., 699; Holyoke, E. A., 534, 540; Hunter-John, 37, 93, 121; Jackson, J. B. S., 439, 514, 521, 569, 584; Larrabee, W. W., 117; Little, 615; Oliver, O. C., 92; Otis, G. A., 211, 261, 333; Percy, D., 129; Ray, I., 332, 353; Rolleston, 616; Russ, J. D., 253; Skoda, 615; Smith, D. P., 24; Spillford, J., 116; Woodward, J. J., 418.
- Bixby, G. H.** A case of hysteroneurosis, 606.
- Blake, C. J.** Middle-ear disease in acute exanthemata, 472.
- Blake, J. G.** Cancer of the cervix uteri, 392, 393.
- Blodgett, A. N.** Case of rare monstrosity, 259; the treatment of strains and sprains by collodion, 234, 301.
- Boardman, W. E.** Travers versus Boardman, an action of tort, 190, 450.
- Bolles, W. P.** Cases of pneumonia, 104, 110; report on the progress in materia medica and pharmacy, 225.
- Bowditch, H. I.** The Isles of Shoals as a summer resort for the invalid, and as presenting a specimen of one of the three climates of New England, 1; case of abdominal disease, 110; correction, 192; presentation of Dr. J. B. S. Jackson's portrait, 514.
- Bowditch, H. P.** The relations between growth and disease, 468.
- Bradford, E. H.** Death from carbolic-acid poisoning following hyperdistention of an abscess with a carbolic solution, 321, 326; recent progress in orthopedic surgery, 413; resection of the tarsus in severe cases of club-foot, 471; false anchylosis of hip-joint, 514.
- Bradford, H. W.** The electro-magnet in ophthalmology, with the description of a new magnet, 232.
- Brooklyn.** Gynecology in New York and Brooklyn, Baker, W. H., 127.
- Brooks, P.** Remarks at dinner of Massachusetts Medical Society, 591.
- Brown, E.** False anchylosis of hip-joint, 514.
- Brown, F. H.** An improved pocket-case, 219; indexes to medical literature, 318; the relations of the Marine-Hospital Service to commerce, the public, and the medical profession, 618.
- Bulkley, L. D.** Diet and hygiene of eczema, 520.
- Burg, G. A.** Chemical analysis of urine, 552.
- Burgett.** Ulceration of the vermiform appendix, 452.
- Burroughs, H.** Phosphide of zinc in the treatment of locomotor ataxia, 211.
- Cabell, J. L.** The National Board of Health and the International Sanitary Conference of 1881, 441.
- Cabot, A. T.** Case of foreign body in the esophagus, 110; case of posterior torticollis, 468.
- Cambell, D.** Case of ovariotomy, 494.
- Campbell, E. R.** The influence of reparative surgery on amputations, 495.
- Capron, G.** Obstetric forceps, 37.
- Castle, A. F.** Podolynia, 419.
- Casswell, E. T.** Case of loose cartilages in the knee-joint, 352; case of litholapaxy, 352; correction, 430.
- Cellular Tissue.** Two cases of subscapular abscess, Hooper, F. H., 85; two cases of subscapular abscess, one of them attended by perforation of the lung, Hooper, F. H., 485.
- Chadwick, J. H.** Revaccination, 189; address on obstetrics and diseases of women, 434.
- Chandler.** Mortality and sickness in New York, 91.
- Channing, W.** The care of insane criminals, 172, 182; recent progress in the insane asylum management and care of the insane, 272.
- Chemistry.** Chemical analysis of urine, Burg, G. A., 552.
- Chicago.** Epidemic of diarrhoea, 92; sewage of Chicago, 92; Illinois training-school for nurses, 115; gastro-intestinal catarrh in Chicago, sewers of Chicago, 260.
- Children.** Anæmia in infancy and early childhood, Jacobi, A., 35; recent progress in the treatment of diseases of children, Hayden, H. J., 59, 81; case of severe laryngeal spasm in an infant, Merrill, F. G., 17, 249; clinical lectures, Jacobi, A., 145, 337; the relations between growth and disease, Bowditch, H. P., 468; infantile eczema, White, J. C., 469; thumb sucking, Goodville, D. H., 470; club foot, Bradford, E. H., 471; middle ear disease in children in acute exanthemata, Blake, C. J., 472; progress in the knowledge of the acute contagious diseases and infections, Jacobi, A., 473; conical cornea, 453; a form of tinnitus aurium induced by a rhythmic contraction of the tensor tympani muscle, 434.
- Circulatory System.** Cephalo-matoma, Fitz, R. H., 63; right hemiplegia after scarlatina, with embolism of the middle cerebral artery, destruction of Broca's convolution, without aphasia, and death from diphtheria, Taylor, F., 94; diabetic coma, its relation to acetonaemia and fat embolism, Fitz, R. H., 124, 132; recent progress in the treatment of thoracic diseases, Knight, F. L., 150, 209; thrombosis of the middle cerebral artery, Wiggles, O. C., 223; a case of diphtheria fatal on the third day from cardio-pulmonary thrombosis and (perhaps) embolism, Curtis, H., 267, 277; cause of embolism of the aorta and iliac arteries of the horse, Peabody, C. H., 332; chronic arteritis of the aorta with unusual course and consequences, Draper, F. W., 421; ulcerative endocarditis, Garland, G. W., 434; blood-letting as a therapeutic measure in pneumonia, Wiley, W. C., 453; connection of cardiac and renal disease, Eeles, R. T., 457, 467; popliteal aneurism following amputation, Allen, C. A., 435; hydrobromic acid, its action on the circulatory and nervous systems, Reichert, E. T., 505.
- Clark, R. K.** A dislocated kidney with cystic degeneration, 188; diabetes mellitus, 285.
- Clarke, A. R.** Perforating ulcer of the duo-duenum, 342.
- Coffin, D.** In-growing eye-lashes, 32.
- Cooking.** New century cooking school, 494.
- Cornell, W. M.** Case of chorea, 85.
- Curtis, C. H. S.** Juglans nigra, a remedy for diphtheria, 226.
- Curtis, H.** A case of diphtheria fatal on the third day from cardio-pulmonary thrombosis and (perhaps) embolism, 267, 277.
- Curtis, T. P.** Binomate of morphia, 34; p. dolynia, its causes and significance, 316, 325; case of diseased bladder and urethra, 328.
- Cushing, E. W.** A case of oily urine with autopsy, 242, 259; epidemic among cows at Colchester, 413.
- Cutaneous System.** The pathology of carbuncle or anthrax, Warren,

- J. C., 5; a case of gumous infiltration of the inguinal glands, followed by a pustulo-cutaneous syphilide, Sturgis, F. R., 108; recent progress in dermatology, Wigglesworth, E., 332; the use of electrolysis in the treatment of hirsuties, White, J. C., 412, 420; infantile eczema, 469; phagedenic ulcers treated by injections of nitrate of silver, Allen, D. G., 501; diet and hygiene of eczema, Bulkley, L. D., 520.
- Cutler, E. G.** Recent progress in pathology or pathological anatomy, 488, 489; case of fibrinous bronchitis, 443.
- Dabney, W. C.** The nature and treatment of pneumonia, 492.
- Dana, C. L.** The benignity of syphilis, 31.
- Davenport, F. H.** A case of urethritis of ten years' standing cured by a single catheterization, 444.
- Davis, N. S.** Pernicious intermittents, 193.
- Digestive System.** Epidemics of diarrhoea in Chicago, 92; pelletierium-tannicum as a remedy for tinea, Steddens, G. S., 33; case of foreign body in the oesophagus, Cabot, A. T., 110; case of abdominal disease, Roaditch, H. I., 110; resection of the stomach, Mixer, S. J., 238, 478; two cases of gout, accompanied by tonsillitis, Forster, E. J., 251; acute jaundice complicating pregnancy, Richardson, W. L., 246; gastro-intestinal catarrh in Chicago, 260; abdominal surgery, 305, 329; mouth washes in illness, Rollins, W. H., 334; perforating ulcer of the duodenum, Clarke, A. P., 342; abdominal surgery, 354; case of intussusception of the large intestine, Putnam, C. P., 373; gastroenteritis and haematemesis, with a case, Warren, E. L., 417; a gall-stone, Rollins, W. H., 419; perforation of the vermiform appendix, Stedman, J., 443; ulceration of the vermiform appendix, Burgett, 452; a membrane-like affection of the bowels, Goss, F. W., 507, 514.
- Doe, O. W.** Hydrencephalocoele, 63; albuminuria in repeated pregnancies, 133; two cases of fibroid tumor of the uterus, 336.
- Douglass, W.** Letter to the assessors of Boston, 1747, 537.
- Draper, F. W.** Recent progress in forensic medicine, 101; rupture of bladder by external violence, 179; chronic endarteritis of the aorta, with unusual course and consequences, 420.
- Driver, S. W.** Relaxation of the pubic ligaments, 249.
- Dwight, T.** Recent progress in anatomy, 241; case of recovery after a large dose of laudanum, 259; frozen sections of heads, 468.
- Ear.** Improved and new powder insufflators, Forster, E. J., 220; an improved ear-spout, Forster, E. J., 249; the Horace Mann School for the deaf, 425; middle-ear disease in children in acute exanthemata, Blake, C. J., 472; a form of tinnitus induced by a rhythmical contraction of the tensor tympani muscle, Chisholm, 494; recent progress in otology, Green, J. Orme, 609.
- Eddy, E. B.** Disease of the prostate, 37.
- Edes, R. T.** Connection of cardiac and renal disease, 457, 467.
- Edgerly, D. M.** A case of sarcoma of the kidney, 131.
- Editorials.** Introductory to 1881, 17; adulteration of food, 17; the proposed organization of the medical service of the company charged with the construction of the Panama canal, 18; kolpecepsitis, 19, 12; the action of anesthetics, 40; prolonged latency of hydrophobia, 41; a real knowledge of insanity and its treatment, 42; the spray in antiseptic surgery, 65; adulteration of food, 66; the governor's address to the Massachusetts legislature, 67; the Harvard Medical School during 1878-80, 88; color-blindness among Connecticut railroad employes, 112; bogus degrees in the United Kingdom, 113; small-pox and revaccination, 137; single and double school sessions once more, 138; Travers versus Boardman, an action of tort and what it teaches, 160; small-pox and revaccination, 161; an antiseptic reply to "Dresser," 162; revaccination, a reply to "Delfoid," 185; the accuracy of clinical thermometers, 186; the New York State Board of Charities, 209; the Massachusetts General Hospital out-patient department, 210; Surgeon George A. OGIS, 211; a bill providing for the examination of railroad employes for color-blindness and defects of vision, 233; revaccination, 234; Bellevue Hospital Medical College, a dishonest reformer, 237; the proposed pharmaceutical law for Massachusetts, 257; the computation of death-rates as illustrated by Baltimore, 257; contragations in insane hospitals, 280, 425; trichinae and cholera in their relations to the American pig, as noted by Consul Crump, 281; abdominal surgery, 295, 329; increase in the death-rates of New York during the last few months, 307; Buchanan the diplomatist as a confessor, 331; Isaac Ray, M. D., L. D., 333; on to Richmond, 354; sparks flying about our powder magazine, 376; the plague in Mesopotamia, typhus fever in New York, 376; the medico-legal relations of hypnotism, 379; biology at the Johns Hopkins University, 377; behold how a little heaven leaveth the whole lump (typhus fever), 401; the resignation of Mr. Webster from the Massachusetts Board of Health, Lunacy, and Charity, 411; the history of abdominal surgery, 402; the Horace Mann School for the deaf, 425; improvement of American public institutions seen through English glasses, 449; Travers versus Boardman, the response, 450; the meeting of the American Medical Association, 475; the relation of soils to health, 496; the arrangements for the centennial anniversary of the Massachusetts Medical Society, 497; two important prizes, 497; the celebration of the centennial anniversary of the Massachusetts Medical Society, 523, 524; an historical and comparative exhibit of medical instruments and books, and of medicines, 523; the Journals' compliments and good wishes to the society, 545; biography of Dr. E. A. Holyoke, 545; the Massachusetts Medical Society's historical exhibition, 594; the Royston prize and the Massachusetts Medical Society prize, 596; athletics and training, 616; skits, Rochester, 616.
- Ellis, C. W.** Remarks at dinner of Massachusetts Medical Society, 583.
- Ellis, G. E.** Remarks at dinner of Massachusetts Medical Society, 592.
- Epess, J. W.** Letter to Dr. Parker, of Virginia, 550.
- Eye.** Notes of changes in the eyes of ten cases of general paralysis of the insane, Williams, C. H., 31; growing eye-lashes, Coggin, D., 32; continued liberation of foreign bodies within the eye-ball for fifteen and twenty-two years, Williams, H. W., 81; a case of congenital total blindness, H. Wiggins, H., 81; color-blindness among Connecticut railroad employes, 112; a strange ocular action on color-blindness, 212; foreign bodies within the eye, and the electro-magnet as an aid to their detection and removal, McHardy, M., 217, 241; a bill providing for the examination of railroad employes for color-blindness and defects of vision, 233; the electro-magnet in ophthalmology, with the description of a new magnet, Brandt, H. W., 235; the eye in disease and other symptoms, Barlt, G. M., 236; recent progress in ophthalmology, Wadsworth, O. F., 314; color-blindness, 427; ocular cancer of the cornea, Fox, the practitioner, Stephens, G. T., 472; how a little heaven leaveth the whole, Holmgren, F., 490.
- Fitch, W. C. B.** A case of ulcer with abnormal presentation, deep
- itation, 133; apomorphia, 327; fracture of the nose, 327; difficult labor, ruptured perineum, 398.
- Fisher, T. W.** Habitual drunkenness, 8, 131.
- Fitz, R. H.** Cephaloematoma, 63; diabetic coma, its relation to acetone-mia and fat embolism, 124, 132; a case of hydrophobia of doubtful origin, 147.
- Fletcher, R.** Prehistoric trephining, 498.
- Flower, A.** An ape-headed nation, 430.
- Folsom, C. F.** The early diagnosis of progressive paralysis of the insane, 558.
- Folsom, N.** Value of scars in vaccination, 262.
- Forster, E. J.** Capacity of spoons, 130; improved and new powder insufflators, 229; an improved ear-spout, 249; two cases of anomalous gont, 251; the necessity of the long nozzle in making intra-uterine injections after confinement, 436.
- Frost, W. G.** Perinephritic abscess, 301.
- Gairdner, P.** Pointmen's work, 166.

Malformations. Deformed pelvis, induction of labor, Richardson, W. L., 245; case of rare oncostosis, Blodgett, A. N., 250.

Mann, E. C. Uterine diseases, 180.

Marey, H. O. The development of the osseous callus in fractures of the bones of men and animals, 201.

Marine Hospital Service. Letter from Dr. F. H. Brown, 618.

Maryott, C. A. Use of forceps and of belladonna, 352.

Massachusetts. Vital statistics in Massachusetts, 70.

Materia Medica and Therapeutics. The Isles of Shoals as a summer resort for the invalid, and as presenting a specimen of one of the three climates of New England, Bowditch, H. L., 1; pure Bourbon whiskey redivivus, 34; the action of anesthetics, 40; the spray in antiseptic surgery, 65; binocerate of morphia, Curtis, T. B., 34; slippery-elm root dilators, Tuckerman, L. B., 46; death under ether, correction, Reeve, J. C., 46; pelletterium-tannicum as a remedy for tenia, Stebbins, G. S., 39; ether in preference to chloroform, Hutchinson, J., 114; hydrate of chloral in cases of rigid os uteri, 133; antiseptic spray, 141; Davos Platz as a resort for consumptives, 201; phosphide of zinc in the treatment of locomotor ataxia, Burroughs, H., 211; cuisine of the sick-room, 212; an antiseptic reply to "Dresser," 162; report on the progress in materia medica and pharmacy, Bolles, W. P., 225; jurgans nigra, a remedy for diphtheria, Curtis, C. R. S., 226; three cases of diphtheria treated with pilocarpin, Vogel, F. W., 228; case of recovery after a large dose of laudanum, Dwight, T., 250; proposed law to regulate the sale of patent and proprietary medicines, Piffard, H. G., 254; the proposed pharmaceutical law for Massachusetts, 257; the proposed pharmacy law, 261; the treatment of strains and sprains by collodion, Blodgett, A. N., 294, 301; apomorphia, Fiffeld, W. C. B., 327; wanted, a solution of morphia, 335; soluble compressed pellets for hypodermic use, Wilson, H. A., 357; a solution of morphia, Lyman, G. H., 357; the use of electrolysis in the treatment of hirsuties, White, J. C., 412; a solution of morphia, soluble compressed pellets, 430; phagedenic ulcers treated by injections of nitrate of silver, Allen, D. P., 501; spina bifida treated by iodine injection, Allen, D. P., 512; hydrobromic acid, its action on the circulatory and nervous systems, Reichert, E. T., 505; the use of olive oil as an external application in diseases of the chest, Parker, W. T., 561.

Medical Education. New York training-school for nurses, 90; the Harvard Medical School during 1879-80, 88; Illinois training-school for nurses, 115; the German private-doctor, 141; Bellevue Hospital Medical College, a disheartened reformer, 237; preliminary knowledge of the classics, 276; biology at the Johns Hopkins University, 377; education of supporters or intended practitioners of irregular and exclusive systems, 491.

Menger, R. Gangrene of both feet, Pirogoff's operation, 109.

Merchant, J. M. Case of protracted gestation, 214.

Metric System. Metric system, Garvin, L. F. C., 37.

Mind. Treatment of the insane, Wilbur, H. B., 21; a real knowledge of insanity and its treatment, 42; insane asylum management in New York, 44; notes of changes seen in the eyes of ten cases of general paralysis of the insane, Williams, C. H., 31; care of insane, Long, J. D., 66; petition of Norfolk District Medical Society regarding care of insane, 155; alcoholic mania in connection with acute disease, Ayer, J. B., 180; the care of insane criminals, Channing, W., 172, 182; recent progress in insane asylum management and care of the insane, Channing, W., 272; conflagrations in insane hospitals, 280, 425; some points in the early diagnosis and treatment of the general paralysis of the insane, Whittemore, J. H., 444; aphasia complicated with insanity, Baneroff, C. P., 483; the early diagnosis of progressive paralysis of the insane, Folsom, C. F., 558.

Minot, F. Mumps, orchitis, 179; cases of lead-poisoning treated at the Massachusetts General Hospital, 221, 230.

Mixer, S. J. Resection of the stomach, 238, 478; notes on the surgical congress at Berlin, 499.

Morrill, F. G. A case of severe laryngeal spasm in an infant, 177, 249.

Mudd, N. M. Cerebral localization, 313.

Mundé, P. F. Use of pessaries, 474.

National Board of Health. Appropriation for National Board of Health, 259; the National Board of Health and the international sanitary conference of 1881, Cabell, J. L., 401.

Nervous System. The relation of the ovaries to the brain and nervous system, Skene, A. J. C., 12; feigned epilepsy, MacDonald, C. F., 21; notes of changes seen in the eyes of ten cases of general paralysis of the insane, Williams, C. H., 31; myelitis, Webber, S. G., 34; prolonged latency of hydrophobia, 41; a case of traumatic epilepsy, Lewis, R. J., 49; hydrocephalocele, Doe, O. W., 63; case of chorea, Cornell, W. M., 56; right hemiplegia after scarlatina, with embolism of the middle cerebral artery, destruction of Broca's convolution without aphasia, and death from diphtheria, Taylor, F., 94; the diagnosis of locomotor ataxia in the earlier stages, Putnam, J. J., 169, 178, 196; phosphide of zinc in the treatment of locomotor ataxia, Burroughs, H., 211; thrombosis of the middle cerebral artery, Wiggin, O. C., 228; eclampsia complicating pregnancy, Richardson, W. L., 247; mesmeric trance, Beard, G. M., 255; stretching of the facial nerve for the cure of facial spasm, Putnam, J. J., 302; cerebral localization, Mudd, N. M., 313; pododynia, its causes and significance, Curtis, T. B., 316; the eye in trance and other symptoms, Beard, G. M., 334; suture of nerves, 354; so-called concussion of the spinal cord, Hodges, R. M., 361, 386; the medico-legal relations of hypnosis, 376; two cases of temporary aphasia, "Bright's diathesis," Roth, T. M., 462, 467; aphasia complicated with insanity, Baneroff, C. P., 483; hydrobromic acid, its action on the circulatory and nervous systems, Reichert, E. T., 505; the early diagnosis of progressive paralysis of the insane, Folsom, C. F., 558; a case of hystero-neurosis, Bixby, G. H., 606; pododynia, Castle, A. F., 619.

New York. Insane asylum management, 44; care of the poor, the sick, and the insane, 67; quarantine, 68; training-school for nurses, 90; mortality and sickness in New York, Chandler, 91; proposed bill to prohibit the vivisection of animals, 114; gynecology in New York and Brooklyn, Baker, W. H., 127; small-pox in New York, 163; sanitary matters in New York, 572.

Noeggerath, E. A new method of performing ovariectomy, 134.

Norman, C. Antiquity of drainage-tubes, 188.

Noyes, C. D. Case of fracture of humerus, 352.

Noyes, H. D. Suit for damages against Dr. Noyes, 68.

Numm, R. J. Suggestions touching the treatment of diphtheria, 470.

Orthopaedic Surgery. Treatment of hip-joint disease, Hutchinson, J. C., 404; recent progress in orthopaedic surgery, Bradford, E. H., 413; case of posterior torticollis, Cabot, A. T., 468; resection of the tarsus in severe cases of club-foot, Bradford, E. H., 471; false ankylosis of hip-joint, Brown, B., and Bradford, E. H., 511.

THE ISLES OF SHOALS AS A SUMMER RESORT FOR THE INVALID, AND AS PRESENTING A SPECIMEN OF ONE OF THE THREE CLIMATES OF NEW ENGLAND.

It is a misnomer to speak of the climate of New England, when in reality it has at least three, namely, oceanic, sea-shore, and inland; each one distinct from the other two, and producing different effects upon man, whether in health or disease.

PRELIMINARY REMARKS UPON THE THREE CLIMATES.

In this paper I shall allude in a most general manner to each one of them, but my chief object will be to bring out, so far as I can do so in this brief article, the beauty, deliciousness, and healthfulness of the climate found at the Isles of Shoals during the summer and early autumn months. I have been for some years a visitor at Appledore (the island earliest used as a sanitarium), and I know of no place more invigorating or more calming to one wearied in mind or body than is found there from early morning until late at night during the whole of the above-named season. Moreover, I know of no place which from its position so many miles from the coast, and at the east

and south fully open to the Atlantic, and with easy communication twice daily with the main-land, presents such an almost unique specimen of one of these three climates, namely, the "*ocean climate*."¹

I hope that, even with this partial account of these climates, I may prevent some of the unhappy mistakes frequently made by physicians and the laity in their choice of places of residence for their patients or their friends.

Invalids or those in health, who come from the far West or South for relief to any real or imaginary ill or mere fatigue, rush vaguely into what they hope to find the curative New England climate. For example, persons having throat or lung difficulties are often ordered by physicians in the West and South to seek the bracing and healing *climate* of New England. Such persons take up their residence in one of the many sea-side hotels and boarding-houses, which line the whole of the New England coast. Nothing can be more unfortunate, for such places almost always do harm to pulmonary patients, though they may renovate or restore persons suffering from other diseases. I have never known a cough to grow less upon our shore. I always take any such patients from the shore, and send them either inland or to the Shoals.

The following diagram explains these climates better, I think, than any more elaborate description:—

THE THREE CLIMATES OF NEW ENGLAND AND THEIR CHARACTERISTICS DURING THE SUMMER.

	GENERAL CHARACTERISTICS.	SUBDIVISIONS.	WHERE FOUND.
OCEAN.	Temperature very equable; <i>rarely sudden changes</i> ; never very hot or very cold. The atmosphere has a peculiar <i>blandness</i> as the predominant characteristic. It is non-stimulating, but rather quieting; rarely enervating. Residence there is like going to sea, without the discomforts of a voyage; soothing, and at times curative, in pulmonary diseases.	No subdivisions possible except those caused either by higher or lower latitude, or by the relative distances of the places from the sea-coast. The Isles of Shoals must, from their position, ever give the best type of a New England ocean climate.	The Isles of Shoals, — <i>purest</i> representative of New England. Monhegan, etc., off Penobscot Bay, higher latitudes, less accessible. Nantucket, too much influenced by Gulf Stream.
SEA-SHORE.	Temperature <i>much more variable</i> ; frequent changes from intense heat to chilliness. The atmosphere has little of the pure ocean blandness, but it varies with the wind. It is at times highly stimulating; at others it debilitates. There is, in fact, from the very nature of the position, a constant contest going on between the ocean and inland climates at every sea-shore residence, always hurtful in pulmonary disease.	No subdivisions, except from latitude and more or less exposure to the sea-breeze, by means of trees, etc., modifying the climate in certain localities.	All sea-side residences, from northernmost point of Maine to the most southern capes and shores of Massachusetts and Rhode Island.
INLAND.	Temperature of medium equability; at times very hot; rarely, if ever, so chilly as the sea-shore; never so bland as the oceanic, because it has no mass of ocean water enveloping it. It braces often; it enervates, at times, under the intense heat, except in the higher mountainous regions; often very soothing; and at certain places absolutely preventive of hay asthma, and beneficial in other lung diseases.	(1.) <i>Low and damp</i> ; bad for all phthical patients, and not healthy for any human being. (2.) <i>Medium and dry</i> . This includes the greater part of New England. (3.) <i>Mountainous</i> . These again may be divided into (a) the open to the sunlight, as Conway, White Mountains; (b) the closed-in valleys, (c) parts in White Mountains where hay asthma cannot exist.	(1.) Interior of the States. (2.) Interior of the States. (3.) White Mountains. (a.) Conway, etc. (b.) Profile House Valley; ² (c.) At Bethlehem and a part of adjacent territory hay asthma is unknown.

¹ There are other islands off the mouth of the Penobscot, for example, Monhegan and Matinicus, etc., all of which may eventually be equally the resort of the traveler, but at present they are virtually inaccessible. Nantucket, being so much farther south, and so influenced by the Gulf Stream, cannot be compared with any of the others. Mt. Desert and all islands so near the coast practically belong to the coast in their climatic characters.

² Whilst preparing this paper a patient appears. For some time he had been inclined to bronchitis, with asthmatic attacks. Last

summer, feeling desirous of resting from overwork in business in this city, he left home, and stopped at night at the Profile House in the White Mountains, intending to stay there. That very night, after feeling oppressed, he had an asthmatic attack. He remained there but two days, all the time becoming worse. Then he left, and though relieved, by getting away, he has never been quite well of his cough and tendency to asthma. He considered that the fact of the Profile House being shut out from the sun till late in the forenoon, and from which the sun departs early, was the cause of his pulmonary trouble.

A proper consideration of the diagram will demonstrate the variability of the coast climate. That fact entirely unfits it for throat and pulmonary diseases, which need, above all things, a bland, equable climate. That of the interior or of the Shoals, in other words, a purely inland or an ocean climate, would be far preferable. Patients recovering from debilitating, non-pulmonary disease and dyspepsia and its hosts of ills may also be benefited under any of these climates. A daily sea bath, which one can enjoy upon our seashore or at the Shoals, is worth a journey of a thousand miles to any of these classes of disease except pulmonary. The warm, open, and dry hills and mountains of our inland climate will relieve them, and this same climate often proves of immense advantage to early pulmonary disease, sometimes, though rarely, removing slight physical signs, often soothing and enabling the patient to *live* longer and with less suffering.

JOURNEY TO THE SHOALS AND SIGHT-SEE-
ING.

My chief object, as I have said, in preparing this paper is not to discuss the values of these three climates, but simply to point them out, and to devote myself to bringing out before the profession and laity of the land the unsurpassed deliciousness of the climate of the Isles of Shoals. If in the middle of a "heated term" in midsummer one gets demoralized in body and mind, and longs to escape from heat and mosquitoes in the city or country, let him seek "the Shoals." In a few days from any part of the land, and a few hours only from any part of New England, he can do so. Let him therefore forthwith shut up his books, and take the nearest railroad or steamboat for Portsmouth, N. H. Arriving there, a short drive or walk (and most persons walk) will bring him to the wharf, where twice daily a bright little steamer will be ready to receive him. Already as he sits upon the deck, and before leaving the wharf, he feels invigorated by the coolness of the atmosphere. He is then about two and a half miles away from the ocean. As he steams down the rapidly running Piscataqua, he will see, while passing the Navy Yard, several dismantled men-of-war lying in peace. They worked well during our late terrible fratricidal but unavoidable fight, and now are at rest. Below the Navy Yard, he will notice various remains of half-built and now decaying forts, which will forcibly remind him how much money has been uselessly spent by the United States on works of no value whatever. On the left, at Kittery, is pointed out the spot where Sir William Pepperell formerly owned immense estates, and whence he sailed as commander in chief of the kings forces for the storming of Louisburg, in 1745.

As the steamer approaches the mouth of

the river, the traveler will feel the cool air of the Atlantic entering his lungs in full draught, and bringing a delightful renewed strength mingled with sense of repose and of freedom from the city turbulence and wearisome perpetual work, or perchance from the dull monotony of country life which he has but just quitted.

In less than half an hour after leaving the wharf, the swell of the Atlantic is felt at the mouth of the river; and if the weather be calm and a gentle, favorable breeze be prevailing, one can anticipate a delightful trip to the islands. They are just visible on the horizon, about seven miles off. If, however, the weather be cloudy and tempestuous, with a strong east wind, it will be well for those liable to be sea-sick to look out for trouble in that respect. An hour and a half or two hours being thus passed either in a delightful excursion or perhaps (but very rarely) the reverse, the steamer reaches Appledore.

FIRST ASPECT, ETC., OF THE SHOALS.

The islands "look," as one writer says, "stern, bleak, and unpromising, yet they are enchanted islands," and there is "an indescribable influence in their atmosphere, hardly to be explained, but universally acknowledged."¹ There are, at low tide, nine of them. The largest (Appledore) contains four hundred acres. Star Island, the next in size, has one hundred and fifty. On these two only were formerly villages. They carried on before the Revolution an active commerce with Europe. The names of two others, namely, Londoners and Malaga, indicate the same fact. People resident at or near Portsmouth would reply to the question, "What news from England?" that the weather had been so bad they had "had no communication with the Shoals, and could not accurately say." Now all is changed. The town at Appledore was deserted by the orders of Massachusetts during the Revolution, as the English cruisers compelled the inhabitants to be neutral. The antiquary can still find remains of cellar walls. The village at Star Island yielded only to modern improvements, and a few years ago all, but one inhabitant, sold their premises to a company for hotel purposes. To the accommodation of invalids and travelers, the Shoals are now dedicated. A steamer plies between Appledore and Star Island. Each island has a large, well-conducted hotel, most admirably managed by the Leighton Brothers & Co.

The islands are so far out upon the Atlantic that the land breeze may be said never to reach them in its intensity.

The Appledore House is the older and more simple hotel; that at Star Island has a lovelier situation and is more fashionable. Appledore is generally occupied by families which have congregated there, and having once tasted the effects of the climate return there every year, and usually occupy the same rooms. They come from all parts of the country, but chiefly, of course, from New York and New England. The simplicity of the earlier times prevails more there than at Star Island only so recently changed from its village state into fashionable life. The small steamer, running as it does every quarter of an hour between the islands, enables friends to visit friends very easily, though living far apart.

THE CLIMATE OF THE SHOALS.

It is very difficult to describe their climate or its effects. Every visitor, after a few days' residence, is in-

¹ Among the Isles of Shoals, John Thaxter Houghton, Mifflin & Co. 1859.

clined to use the language of hyperbole when alluding to the wonderful blandness and uniformity, mingled with a peculiar clearness and cleanness, so to speak, of the atmosphere, which prevails there from early morning until late at night. There are very few insect tormentors, such as infest the inland and coast. The dreadful east wind of the coast seems unknown there; for although the wind may come from the east, it never has that peculiar "goose flesh" chilliness, which we notice when on the sea-coast. As one sits upon the long piazza of Appledore some bright, sunny morning in summer, and feels the soft sweet air touch his cheeks, while he inhales it in all its purity, he can readily imagine the effect of it upon body and mind to be similar to that which poets describe as produced upon the lotus-eaters who, when indulging in their favorite food, forget even their country. The visitor tends to feel at peace with all mankind, and to forget the troubles that have beset him on the continent. Mere existence is a supreme delight. He watches the surging of the sea, the perpetual swaying of the Atlantic waves upon the granite-bound border of the island. If he be young he may try to see the magnificence of the sunrise over the Atlantic. If older and more sedate, he still can enjoy extremely the superb sunsets over the New England coast. Every one seems to revel in a present enjoyment of a real comfort of body and soul, such as he has never felt before.

In using this strong language I do not deem myself as indulging in a poetical license, but merely stating, as it were, a simple scientific fact. I have never breathed anything like it in this country or in Europe.

In confirmation of these statements, I am allowed to quote the following letter, written by a gentleman at my request. The writer is a wise, practical, man, and constantly occupied, when not at the Shoals, as the head of an extensive business house in one of our large cities. I deem his testimony very valuable, because he has tried the *three climates*, which I have laid down as the climates of New England, and he has found none of them equal to that of the Shoals.

"DR. HENRY I. BOWDITCH:

"DEAR SIR,—In accordance with your request I would say that an inland climate, especially in mountainous districts, has always been exhilarating to me, and except in very high altitudes, like Mt. Washington, or in the vicinity of the Rocky Mountains, where I am troubled with a shortness of breath, I always find quicker recuperation, and I enjoy the country better than the sea-shore.

"When I first came to Boston the climate of the sea-shore was very depressing to me, and seemed to bring with it a sense of loneliness and general depression. Twenty-five years ago I had a bronchial difficulty, with a slight cough; the sea-shore was then very trying. Since then, my general health being better, it has not troubled me so much, but I have always an instinctive dread of the sea-shore. While at the Shoals for the two seasons that I have spent there the atmosphere has seemed to me *neither exhilarating nor depressing, but very pleasant.*"

I italicize the last words because they seem to express my own feelings, only in a more quiet, philosophical style.

WHAT CASES SHALL WE SEND TO THE SHOALS?

I reply, *Any* case, whether functional or organic, I think may be sent there without *evil* result. Of

course, I do not include any *totally hopeless* cases of *far advanced* organic disease. Although I have never seen pulmonary difficulties absolutely cured there, they have been relieved and quieted,—a circumstance which I have never met at the sea-coast. Mild (non-tubercular), simple bronchitis I should advise to be sent there, with hope of permanent relief. Early phthisis receives no harm. Sometimes strength is gained. One person with hay asthma (autumnal catarrh), and the only patient with that disease I have met there, had been for many years wholly relieved of her severer symptoms, and only occasionally did she have the slightest dyspnea, when the west wind had been blowing from over the land, from the coast, for several days in succession. For her the Shoals acted as well as Bethlehem, or any of the places in the White Mountains and elsewhere at which hay asthma is virtually annihilated.¹

Persons recovering from any acute disease would do well to try the Shoals. Some nervous complaints, dependent on debility or overwork, may be almost sure of benefit. Dyspeptics will find fresh air and pleasant exercise in the yachting and rowing afforded there. On one of the islands, occupied solely by fishermen, is one of the prettiest of beach bathing places. There the water is deep and clear. The shore shelves off gradually over a white bottom. One can see to the depth of twelve or twenty feet with perfect distinctness. It is now wholly unused by travelers. Other beaches can be found on other islands. Within fifty years I believe that all the habitable portions of all the islands will be studded with hotels and private villas. These latter will belong to rich men, who, seeking for comfort and for coolness and blandness of climate during the summer, will go there as to almost the only place in this country, where such qualities of climate can uniformly be found.

I adjoin records of the weather kept last summer, at the Shoals and at the Navy Yard at Portsmouth, from which one can judge still more clearly of the characters of the two climates. An examination of the record by days will show how little change takes place at the Shoals.

The temperature there generally ranged between 60° F. and 80° F. Once or twice only did it rise to 80° F., and once in September it fell to 57° F. United with these records are others procured for me, by the courtesy of E. G. Pierce, Esq., postmaster at Portsmouth, from the records kept at the Navy Yard during the same time.

The comparison of these records day by day will give a graphic idea of the difference between the two climates (ocean and coast). Especially I would draw attention to the last two columns, namely, those showing the variations of the daily temperature, and the mean daily temperatures.

THE PATHOLOGY OF CARBUNCLE OR "ANTHRAX."²

BY J. COLLINS WARREN, M. D.

A GREAT deal of confusion has arisen owing to the unfortunate application of one name, anthrax, to two entirely different diseases. The existence of an inflammatory mass in the skin, in each case accompanied by gangrene and constitutional disturbance, which

might terminate fatally, led many authors to confound the affections, and although at the present time the fact is well recognized that the fever of a malignant pustule is a specific one, and that of carbuncle merely pyæmic or septicæmic, the names are still largely common to both in most languages. Anthrax, the term originally given to the specific fever of animals, may be translated into murrain or splenic fever (English), *milzbrand* or *carbunkel* (German), and *charbon* (French). Malignant pustule is the name given to the last named disease, when occurring in man, by English and German writers, and occasionally by the French, although *charbon* covers both in the language of the latter. Anthrax is still used by veterinary surgeons as the scientific name for the specific fever, but it is not used in this sense by the prominent surgical writers³ of to-day, who employ it to designate the local inflammation of the skin under consideration. The English "carbuncle" is synonymous with "anthrax." It is a term not employed by the French; by the Germans it is used indiscriminately to denote either disease.

The current authority on surgical pathology⁴ thus describes carbuncle: Anatomically it resembles a group of several furuncles lying close together. Its origin and first stage are the same as in furuncle; that is, the death of a small portion of the skin (perhaps a cutaneous gland) seems to be the starting-point and centre of the inflammation. "Soon a number of white points form near each other, and the swelling, redness, and pain in the periphery increase in some cases so much that the carbuncle may attain the size of a soup-dish; and while the detachment of the white plugs of skin goes on in the centre the process not unfrequently extends in the periphery. . . . After the loss of the plugs of cutis, the skin appears perforated like a sieve. . . . But even when most intense, the process is almost always limited to the skin and subcutaneous cellular tissue. . . . You will have already noticed that the process of formation of furuncles and carbuncles differs from the inflammations with which you are already acquainted by the constant and peculiar death of portions of the skin. Of course, this must be induced by an early, perhaps primary, occlusion of small arteries; possibly of the vascular net-work around the sebaceous glands. . . . This limitation to the skin and subcutaneous cellular tissue is very characteristic of fibrinous (diphtheritic) inflammations; so that on this account, as well as from the hard infiltration and necrosis of the tissue once infiltrated, I do not hesitate to consider carbuncle as a diphtheritic inflammation of the skin. . . . Kochman thinks that carbuncle as well as furuncle originally develops from a sweat gland or from several adjacent glands. J. Neumann distinguishes between carbuncles from sweat glands and from cellular tissue." In Neumann's book I find no such distinction.

In the *Nouveau Dictionnaire de Médecine et de Chirurgie* it is defined as an inflammation of the subcutaneous cellular tissue, with a tendency to mortification of the skin. The author believes that the affection begins ordinarily in the cellular tissue lying between the fascia and the skin. It differs only from a furuncle in the extent and depth of its inflammation. In Holmes's *System of Surgery* it is also described as attacking the subcutaneous tissue and involving the skin.

¹ Autumnal Catarrh, Hay Fever, by Morrill Wyman. Hurd and Houghton, 1872.

² Communicated to the Boston Society of Medical Sciences.

Mr. Ledwick¹ gives the following summary of views on the pathology of this affection: "There is much discrepancy of opinion in relation to the precise seat of this disease at its commencement. Rokitsansky² believes the affection has its origin in the deep layer of the corium, involving the areolar tissue—deep layer of and subsequently extending to the subcutaneous structure. Brodie³ remarks that the disease may commence in the elongations of the cellular membrane. . . . Dupuytren⁴ believes that the dermoid prolongations of the areolar tissue, which become strangulated, are the peculiar localities of the disease, accounting thus for the cribriform suppuration of the skin and subsequent sloughing; whilst Hunter⁵ insists that its source is always tegumentary, and spreads to the cellular tissue. . . . Nélaton⁶ teaches that an anthrax is rather subcutaneous than cutaneous. I have not the least hesitation in affirming that the primary hardening is subcutaneous, spreading, as the disease advances, from the deep to the superficial surface of the skin, which ultimately participates in the gangrenous affection." Mr. Collis,⁷ writing on this point, says it is essentially an inflammation of the dense fascia in which the superficial areolar tissue is implicated, as in furuncle, and also the deep, as in phlegmonoid erysipelas.

Dupuytren appears to have had the most accurate knowledge of the anatomy of the part affected, and hence the clearest views as to the seat of the disease. He defines anthrax as an inflammation of several bundles of cellular tissue contained in the areolar spaces of the skin. These spaces are formed by the interlacing of bundles of fibrous tissue, and the cellular tissue contained in them is frequently filled with "fatty fluid." They have a cone shape, the base being at the lower border of the skin and resting on a layer of cellular tissue, the apex terminating in a number of little holes directed obliquely in the skin.—easily demonstrated in a specimen which has been macerated for some time. Anthrax consists, he thinks, in an inflammation of these bundles of cellular tissue, and is found where they are most perfectly developed.

A glance at the anatomy of that portion of the skin where carbuncle most frequently occurs, namely, that of the upper dorsal region, will serve to explain many of the striking peculiarities of this affection. In the first place, the skin is extremely thick; probably thicker than at any other portion of the body. It forms a solid mass of dense fibrous tissue, well calculated to sustain burdens or to protect a comparatively defenseless portion of the body. The great bulk of the cutis vera necessitates certain important modifications of contained and contiguous structures. The hair follicles, being those supporting downy hair only, and therefore shallow, project but a short distance into the uppermost layers of this mass of fibre; and there would be no communication with the subcutaneous adipose tissue were it not for oblique columns of fat which extend from below to their bases. These fat columns, or *columnæ adiposæ*, which I have described elsewhere,⁸ are found beneath each hair folli-

cle, are of about the same width, — perhaps a little broader, — and contain, besides loose connective tissue fat cells and vessels, the coil of a sweat gland suspended midway in the shaft. (Figure 1, *e*.) There are generally two horizontal branches to this cleft (*p*) in the skin, and I have already shown how an injection mass forced in from below may ramify through the whole thickness of the cutis, forming quite a delicate net-work, and marking out the anastomosing system of lymphatic channels. At the point where these columns open into the parts immediately below this dense sheet of cutis we find a broad band of fibrous tissue (*k*) given off from one side and extending down obliquely into the subcutaneous structures, to be attached finally (tendon like) to the fascia, beneath which lie the muscles. These fibrous bands interlace one another in various directions; are very different in character from the delicate "cellular tissue" underlying other portions of the skin, and form a dense net-work, which holds firmly in place the tough hide to which it is attached. (Figure 4.) In the interstices there is the usual loose connective tissue, which is largely occupied by fat cells. Dissecting students are familiar with the toughness of this subcutaneous layer, as also any surgeon who has once attacked a lipoma in this region with the vain hope that it was going to "shell out" easily (*g*). It will be observed that the alveoli formed in the mesh-work, although having a comparatively limited communication with the neighboring subcutaneous structures, have a tolerably direct, though narrow, medium of communication with the surface through the fat columns, which chimney like are placed directly above them. These columns are evidently none other than the "holes" alluded to by Dupuytren, who, so far as I am aware, is the only observer who has in any way suspected their existence.

The characteristic features of the carbuncular swelling are its broad, flat, indurated base, the cribriform surface of the skin, and the honey-combed appearance of the subsequent crater. These appearances I have had an opportunity of explaining by the microscopical examination of large sections of skin and subcutaneous tissue removed from the borders of several specimens of carbuncle.

The earliest changes seen at the extreme periphery are scattered collections of wandering cells in the subcutaneous adipose tissue, and as we approach the centre we find clusters of these cells in the *columnæ adiposæ*. These cells appear to follow some of the numerous natural channels of the tissue in their progress, probably the lymphatics. There is nowhere any well-defined boundary to the inflammatory tissue. As we proceed inwards the cells become more numerous, until the entire subcutaneous tissue is occupied by them; at this point the columns of the skin are already filled at their bases with the round cells, while a few rows of cells extend to the apex. When we come to the point where the columns are entirely filled with cells we begin to observe an infiltration of other portions of the skin, which are reached through the lateral horizontal clefts branching on either side from the columns midway from base to apex. (Figure 2.) In these clefts we usually see a blood-vessel, around which lie the cells in abundance; by finer subdivision of the clefts (*p*) the cells penetrate interstices of the fibrous tissue both upward and downward, until the whole of the deeper portions of cutis vera is completely infil-

trated (*m*). A thin, superficial layer still remains intact.¹ Meanwhile the inflammatory cells, having reached the apex of the column, are brought to a momentary halt, but soon find their way to the superjacent papillæ around the edges of the hair follicles and along the borders of the erector pili muscle. By this time the column has been much distended and elongated, the whole cutis having become swollen. The adipose tissue has entirely disappeared, (*m*) and later also the hair follicle and muscle, all that is left being the hair shaft, which is now seen projecting and forming a prominent pustule. It is at this point, therefore, that the pus first appears upon the surface. (Figure 2, *h*; Figure 4, *h*, *m*.)

At this stage of development of the carbuncle the papillæ of the skin covering the tumor present appearances which deserve special attention. (Figure 3.) At those points where cell infiltration is most abundant a change of shape is occasionally noticed, the upper part of the cone becoming greatly distended, so that the narrowest portion of the papilla is its base, the cone being converted into a balloon-shaped figure (*h*). A more minute observation shows that papillæ thus affected contain a number of wandering cells, and that the meshes of their loose tissue are distended with fluid; they have the appearance of being oedematous. The adjacent layers of the rete mucosum are greatly compressed by this swelling, and in some instances the interjacent projections of the deep layers of the rete are nearly obliterated, several neighboring papillæ thus becoming united to form a single large one. Usually, however, we find that the number of cell elements in the papillæ gradually increase, until it becomes packed solid with small round cells, which obscure all other structures. The blood-vessels, if seen, are filled with red blood corpuscles, which are also found at times in considerable numbers in other parts of the papilla. At this stage we find that the fundus of the polypoid structure presents itself above the level of the surface, the epidermis forming but a thin layer above, or being represented by a few adherent crusts and scales. The final stage in the development of this series of changes is an actual giving way of the epidermal covering, and an escape of the contents of the papilla. Should the epidermal covering continue firm the contents of the papilla undergo retrograde changes, and we find, in fact, many containing a shrunken mass of detritus, the anatomical structures of the part having been completely destroyed. In short, we have here an example of the mode of development of the minuter form of pustule which is found scattered in such profusion over the surface of the carbuncle. The cutis beneath these pustules is unusually well supplied with wandering cells, and in specimens treated with picricarmin we find also most perfect examples of the division of the fixed or the epithelial cells of the connective tissue. (Figure 3, *f*.) Indeed, in no other tissue can the various stages of the inflammatory changes of connective tissue be studied to better advantage. So far as I am aware no such description of the development of certain forms of pustules has ever been given, but the appearances described are too constant and correspond too accurately with the pustules seen on the surface of the specimens examined to admit of other interpretation. In the ordinary acceptance of the term, it

may be objected that these collections of pus in the papillæ should be regarded as genuine pustules, as they are not the result of a purely isolated and local process, but are merely the terminal points at which pus makes its escape from the skin through which it has forced its way from below, as in the case of the channels already described. That many so called pustules in other localities may, however, be formed in this way will be a point for future investigations to determine.

Finally, as the inflammatory process continues, the spaces between the bundles of fibres of the cutis are much enlarged, and the fibres themselves seem to be partially absorbed; the tissue becomes so brittle that it crumbles readily under the razor. By this time the plug of cells occupying the column has softened to a semi fluid mass, and is retained in place only by a thin layer of cuticle, which still forms a covering to what has now become a large pustule. (Figure 4, *h*, *m*.) In the subcutaneous tissue the cell infiltration has spread from one alveolar space to another, while the tendon-like bands of fibrous tissue appear to be but slightly affected (*m*); in fact, the cells do not penetrate them at all, but when the surrounding parts are melted into pus they form the undetached masses of sloughing tissue which hold down at first the integument, and favor spreading in a lateral direction, and at a later stage give to the crater its honey-combed appearance.

In specimens of carbuncle of the lip sections taken from various portions showed the same tendency to a diffused cell infiltration of the structures.

The papillæ in this case also are worthy of notice, although naturally diverse in shape and size, and crowded between large hair follicles, their alteration by the inflammatory process is evident. In some cases the papillæ are distended by a mass of small round cells, and where this cell infiltration is most marked we find extensive ecchymoses at the apices of the papillæ, showing that considerable disorganization of the tissue at that point has taken place.

In the light of these observations it seems unavoidable to abandon the old view that a carbuncular inflammation is one originating or developing itself in a number of adjacent foci, and to conclude that we have a more or less rapidly spreading phlegmonous inflammation of the subcutaneous cellular tissue, we might say a *purulent infiltration*, the characteristic appearances being produced by the anatomical peculiarities of the part affected. In confirmation of this view, attention may be called to the fact that the more distantly removed from the region where the structures described exist in their most highly developed form, the less typical is the appearance of the disease. When seated upon the anterior aspect of the body there is little to remind one of its striking characteristic. On the other hand, when an abscess, that is, a circumscribed collection of pus, forms in the dorsal region, a protective barrier of cells is thrown around the accumulating pus, there is no infiltration of the tissue, and the pus reaches the surface by pressure upon the superjacent integument, which, softened by inflammatory changes, melts slowly away before it. There is in such a case no injection of certain structures with pus, as in carbuncle, and the characteristic appearances of the latter affection fail to show themselves. The cribriform appearance is also not typically developed where the skin is thin and the columns do not exist, as in carbuncle of the lip. The pus then leaks through, so to speak, only at one or

¹ In making injections of Prussian blue by pressure from below against the under surface of a portion of normal skin, I found great difficulty in forcing the mass into the upper fourth of the cutis, although the injection ran well below.

more accidentally less-resisting spots, taking as a route one of the lymph spaces of the cutis, and reaching the surface through a papilla.

HABITUAL DRUNKENNESS.¹

BY THEODORE W. FISHER, M. D. HARY.

THE preceding cases are sufficient to show the chief characteristics of the class of habitual drunkards with which I have to deal. It has been the custom for twenty years, at least, to send selected cases of this class to insane hospitals in this State. The McLean Asylum, being a corporate institution, has usually declined to admit them. The trustees of state hospitals, while recognizing the annoyance their presence causes among more manifestly insane patients, in various ways, have always received and attempted to retain them long enough to effect an improvement, if not a cure. Individual trustees of most of the hospitals, Danvers included, have frequently requested the commitment of habitual inebriates in whom they had some personal or humane interest. The trustees of the Danvers Hospital have, however, recently asked the committing authorities not to recommit certain cases of habitual periodical and dangerous drunkards to that asylum. The claim is not made that these cases were not insane when committed. If the state hospitals should all be closed to this class of patients, a certain risk to the public safety would result, since cases of mania from drink could not be brought into court on a charge of drunkenness. No delirious or temporarily insane person is in condition to plead to an indictment. Delirium tremens being a self-limited disease of a few days' duration, and capable of exact diagnosis, persons having it can be safely sent to Deer Island or Tewksbury for treatment. Mania from drink, on the contrary, is of indefinite duration, and, the diagnosis being more difficult, some judicial process is desirable before commitment.

The State Board of Health, Lunacy, and Charity, last summer, issued blank forms to physicians throughout the State, requesting information on the hereditary influence of the use of alcohol. I am informed that the replies have been few and unsatisfactory; partly from negligence, no doubt, and partly from the lack of complete family histories. The form of the questions requires numerical answers in most instances, and classification of cases as excessive, occasional, periodical, or habitual drinkers. A person may have been each in turn, and doubt would naturally arise as to his proper place in the catalogue. The periodical drunkard is, by the terms of the circular, alone considered insane, while most authorities on the subject regard dipsomania as acute, periodical, or chronic, and insanity may coexist with any form of habitual drunkenness. To avoid the difficulty of tabulating cases, I sent brief statements of the essential facts in as many cases as were sufficiently complete to be of any value, and I would suggest to other physicians to do the same, and hereafter to make such full inquiries in all cases as the circular calls for.

My observation shows that certain defects occur in the descendants of habitual drunkards with greater or less frequency. These are: (1.) All the forms of drunkenness enumerated. (2.) Nearly all the known

forms of insanity. (3.) All degrees of congenital mental weakness from slight moral deficiency to complete idiocy. (4.) Various forms of nervous disorder, such as epilepsy, hysteria, chorea. (5.) Certain bodily defects, as blindness, deaf-mutism, scrofula, and phthisis. The comparative frequency with which these diseases are preceded by ancestral inebriety is important, but not easy to determine, as well as the occurrence of defects in the descendants of drunkards. The questions of the State Board were intended to bring out the negative as well as the positive evidence, and to show how many such descendants escape. The constitutional diseases and defects of body and mind in children which so often succeed drunkenness in parents, in the experience of many physicians, naturally go a long way to convince them of a direct causal relation.

Other questions of the circular related to the origin of drunkenness itself. In how many cases was it hereditary? In how many due to moderate drinking, to wine on the table, to physicians' prescriptions, to the use of beer, or to grief and depression or excitement? The latter question is especially important, going as it does to the root of the matter in many cases. So intimate is the relation between inebriety and mental depression that periodical cases sometimes appear to consist in a genuine *folie circulaire* exhilaration, excitement, and indulgence in drink, with maniacal symptoms as a result; being followed by depression and exhaustion, with an interval of sobriety, and after a brief period of irritability by mania, depression and sobriety again. It is certain that grief and depression are often direct causes of an attack of drinking. Insanity of a melancholic type is sometimes met with in the immediate ancestry or among brothers and sisters of an inebriate, suggesting strongly a common origin of the habit and the disease in an inherited neurotic constitution.

I will give with some detail one more case, interesting from a medico-legal point of view. A suit was brought two years ago in the Massachusetts Supreme Court by Jason L. Blodgett against his divorced wife, Major Jones, now on the Board of Police Commissioners of Boston, and Drs. Fisher and Youngman, for a conspiracy to imprison him in the Taunton Lunatic Hospital on the false charge of insanity; also for assault and battery in causing his arrest; and for taking his property, ruining his business, and causing great damage to his reputation and feelings; for all of which damages to the extent of \$15,000 were claimed. His legal adviser at first was William H. Towne, who afterwards called to his assistance Edward Avery. The defendants were represented by Edward P. Brown. At the first trial the plaintiff's petition was dismissed for informality and illegal contents. Major Jones was excused, as having had nothing to do with the particular commitment complained of, the plaintiff having been sent to Taunton twice; and Mrs. Blodgett, having been his wife at the time of the alleged offense, could not be proceeded against. This left the two physicians standing alone; and, after six months, the case was called again, unexpectedly, at the close of the summer vacation, when police officers, who were important witnesses, were absent. The wife, whose testimony was almost absolutely essential to the defense, had hidden herself from her divorced husband in the far West, and could not be compelled to attend or obtained as a witness without great expense. The plain-

¹ Concluded from vol. ciii., page 636.

tiff told a story, based on his confused recollection of events, and deliberately false in some parts, which was contradicted by the defendants, who offered to put in as the basis of their certificate information received upon "due inquiry," as well as the result of personal examination. This hearsay testimony, though required by law as part of the foundation of the certificate, was not admitted in its support at this time, and, the wife being absent, essential facts were kept out of evidence. The rulings of Judge Endicott were in every other way favorable to the defendants. The jury disagreed, as the foreman afterwards stated to Major Jones, by permission of the court, — nine for the defendants and three for the plaintiff, on the question of "lack of due inquiry" only. No suspicion of a conspiracy was entertained by any jurymen.

The case was again called last spring, the wife still being absent. The plaintiff, with one or two unimportant exceptions, was his own witness, and made the same or similar false statements as before, showing clearly on the stand to medical observation the unreliable and irresponsible nature of his mental operations. The case was classified as dipsomania on all the certificates offered, of which there were three. The following is a brief sketch of the plaintiff's history: —

At the time of the trial he was a man about forty years of age, of evidently neurotic constitution, impulsive, excitable, with a loose way of expressing himself, said to have been characteristic of him from youth. One witness testified that he had always been given to telling untruthful and inconsistent stories. He was reported to have had an aunt who was insane. His father was a clergyman, and both his parents died in his early youth of consumption, leaving him in charge of his relatives. He was a bad and irregular scholar, though quick-witted enough for mischief. At the age of puberty he showed a proneness to premature vicious conduct of various kinds. He is said to have begun to drink by sprees at the age of fifteen years. He had some good traits and impulses, but was early the slave of his appetites, and was cursed with a craving for drink. His sister says he was a good brother when sober, but a "perfect devil" when drunk.

He was in frequent trouble on account of his scrapes, both in the country and in Boston, until the war broke out, when he enlisted. Having previously lost the sight of one eye, it was still further injured by a thorn, and was enucleated. He was then put on an army freight train as conductor or brakeman, and continued to serve until the close of the war. After the war he was employed on railroads at the West, leading a life of active dissipation, according to his own admission to a witness. In 1875 he came to Boston, claiming to have reformed, and that he was the possessor of a large sum of money. In this belief a widow of the former proprietor of certain Turkish baths in Boston — herself being the owner at that time — married him. His fortune proved mythical, and his wife was obliged to pay for his wedding suit and for the wedding journey; she gave him a gold watch, and supported him ever afterwards, except for the small value of his services in the baths. He obtained control of all her property, and in a very short time developed a tendency to drink by sprees, in which he was ugly, violent, and dangerous, threatening his wife in particular. He was seldom seen drunk in the ordinary way, but was exalted and maniacal, acting more or less automatically, and failing to remember his conduct and

conversation afterwards. It is but charitable to suppose that this accounted for his wholesale denial of numerous facts testified to by a score of witnesses on the stand. In a year or two he had spent all his wife's property and destroyed her business by his drunken conduct.

My attention was first called to him October 12, 1875, by Dr. A. N. Blodgett, his wife's physician, but not related to either party. Dr. Blodgett, being in attendance on the wife, found the husband in a state of delirium from drink, in which hallucinations of snakes in his bed were prominent. He thought he saw the devil in the looking-glass; threatened to kill his wife; threw furniture violently about the room; and did not recognize Dr. Blodgett, but violently assaulted him several times. Policemen were called, and he was taken to the tombs. The next morning application was made by Dr. Blodgett to the Board of Directors for Public Institutions for his commitment to Taunton as insane. Having learned his previous history, I agreed that he might be a dipsomaniac, but, the present attack resembling in some of its features delirium tremens, advised that he should be sent to Deer Island. He did not have a perfect attack of that disease, and was discharged in two or three days, apparently rational.

He was again arrested January 31, 1876, for violent conduct while drunk, and released on promise of good behavior, but was rearrested the same day, fined three dollars and costs for being drunk, ten dollars and costs for assault on a female employee at the baths, and was bound over for six months to keep the peace. Was sent to jail, and Major Jones, as bail commissioner, signed the bond on which he was released. June 24, 1876, was arrested again, but let off on promise of good behavior. Again, on November 8, 1876, he was arrested as insane. Complaint having previously been made to the board of directors, I was sent with Dr. Youngman to interview Blodgett. Learned that he had been very violent at the baths, smashing up furniture and frightening bathers and employees. Found him at home, an officer bringing him up from the cellar, where he had retreated, having an axe in his hand. His wife had fled from the house, and the other inmates were locked in their rooms. He was in a very ugly, sullen mood, having been drinking heavily. He denied, as was his custom, ever drinking to excess or using violence to any one. He had recently had a spasm of religious interest; went into a prayer-meeting at the Young Men's Christian Association, and offered any brother twenty-five dollars to convert him. A member went home and prayed with him, but was turned out by Blodgett because he "didn't pray worth a damned cent"! No sign of delirium tremens was present at this time, and it was determined to send him to Taunton as a dipsomaniac, with a view to a sufficiently long detention for his improvement or cure. He made no objection and asked for no hearing, thus acquiescing in his commitment.

Having remained at Taunton a few weeks, he was discharged on application of his counsel, Mr. Towne, and was sober and well behaved for a considerable period after it. He admitted, in an interview with Major Jones, his irresistible disposition to drink, and that he presumed the allegations of violence were true, but that he did not remember what occurred at certain periods of his drinking spells. He had also cou-

sulted a relative in reference to some cure for his entire loss of self-control in reference to drink. He joined the church of which his wife was a member, and behaved well till August, 1877. From August to December he had three sprees, in which his conduct was erratic and violent. For instance, he would rush down Washington Street in the evening with a roll of bills in his hand, flourishing them about, and followed by a crowd of men and boys. He would buy a pie, order a hack, and send the pie home alone in the hack. On several occasions he used vulgar, profane, and threatening language to ladies at his wife's boarding-house. December 10, 1877, complaint having been made to the board of directors, he was examined at his boarding-house by Dr. Youngman and myself. We found him in bed, nervous and confused, as if from a prolonged debauch. I talked with him half an hour, explained to him my theory of his case, told him I thought nothing but prolonged detention would do him any good; that as he had improved after a few weeks in Taunton a year would do him still more good. He denied drinking more than was good for him, but said he would stop at once if we would not certify in his case. I told him if he was arrested again for violent conduct I should certify. This interview, he testified, was only a few minutes long, and he could remember but one thing that was said. Two days after he was arrested at the baths for furious conduct towards his wife and other ladies, and for trying to kick over a hot stove. He was sent to Taunton December 12, 1877, and asked for no hearing at this time.

Remaining in Taunton about three months and a half, he was discharged March 26th, and rearrested for throwing a bottle at some one at the baths March 30th, four days after. The next morning he showed very little effect from liquor when seen at the tombs, the period of indulgence having been brief. He demanded a hearing at once, and a certificate *pro forma* having been signed to bring his case before Judge McKim, he was released on promising good behavior. In April a libel for divorce was filed by his wife, alleging brutal and violent conduct, with gross and frequent intoxication. Blodgett appeared in the anteroom of the supreme court in his usual peculiar condition, insulted several ladies there with obscene talk, undertook to conduct his own defense, and harangued the court in such strange and familiar language that the judge told him he must be either drunk or crazy, and granted the divorce. His wife then left him for the West, in a penniless condition, and he soon found a lawyer willing to take his suit against the alleged conspirators. This idea of a conspiracy was, I think, in part a vague delusion growing out of imaginary wrongs, and in part a foolish attempt to rehabilitate his fortunes and revenge himself at the same time by a suit against his assumed enemies. A few weeks before the final trial he was arrested for drunkenness in Waltham, and boasted, in his loose way, of the immense business he was doing, and of the money he was going to make out of the doctors.

At the last trial, before Judge Lord, the preceding facts and many others of similar import were proven. Twenty policemen testified to Blodgett's habits of drunkenness, eccentricity, and to his violent actions. They all agreed that he was different from ordinary drunkards in his talk and conduct, and was regarded as crazy and dangerous when in liquor. This opinion

was sustained by many other witnesses who knew him well, and by his own confessions to Major Jones, as well as his appearance on the stand. He there denied in a wholesale way all excessive drinking and all acts of violence, only to be contradicted by many reliable witnesses. He might, perhaps, truly have said that he remembered no acts of violence, as I have no doubt his conduct was automatic. Judge Lord allowed the facts obtained by "due inquiry" to be testified to in full, the other side failing to object.

A number of experts were called by the defense. Drs. Walker, Brown, Gage, Russell, Denny, Jelly, Folsom, Channing, Day, Blodgett, Fisher, and Youngman gave their definitions of dipsomania and testified to the propriety of treating it in hospitals for the insane, in the absence of other special institutions. These gentlemen substantially agreed in affirming the existence of such a disease and in the necessity of so treating it.

The plaintiff called on his behalf Drs. Henry G. Clark, J. P. Treadwell, and Horace Chase. Dr. Clark thought a dipsomaniac must be a person who on drinking a single glass must inevitably go on to complete intoxication. He thought Blodgett did not fall within this definition. He was obliged to admit, however, that he had recently said that Blodgett was "crazy drunk" and properly sent to Taunton, but was kept too long; and that he had certified within three months in the case of a dangerous dipsomaniac committed to Danvers. Dr. Treadwell gave his views at length, and thought the part of the testimony he had heard did not warrant calling Blodgett a dipsomaniac. Dr. Chase's testimony I did not hear.

Judge Lord's charge to the jury was satisfactory in every way to the defense, and was an admirable statement of the rights and liabilities of physicians certifying in cases of insanity. It deserves reproduction as a whole, but I will give only a very brief abstract of it. Judge Endicott had said in substance at the previous trial that it was evident from the testimony that there was such a disease as dipsomania; that the line between it and ordinary vicious drinking was a narrow one, which only qualified medical men could safely draw; and that a lunatic hospital was a proper place for its treatment. Judge Lord, however, told the jury to reject the technicalities of the doctors, and charged that if mental un-soundness of any kind existed it was an end of the case; that if physicians honestly believed the party to be insane, although they may have been misled or mistaken, they were not responsible. They were obliged by law to make "due inquiry" of the parties most likely to possess the facts relating to insanity, and nearest by ties of relationship or affection to the patient; but they could not take sworn evidence in the case, and must act according to their best judgment upon the facts obtainable. Their certificate was not required by law to be under oath, and was merely the necessary means of bringing the case into the jurisdiction of the proper court, after which they were not responsible for the action of the court, unless it could be shown that they willfully gave false testimony, or grossly and criminally neglected to inquire into the facts of the case. In the words of the court, "If capable physicians should act recklessly, disregarding the rights of the party, and send him off to a hospital without any evidence at all, then they would be responsible. But if, on the other hand, they made the inquiry which the circumstances of the particular case

called for, then although subsequent events may show that that inquiry might have been pursued further, if they acted in good faith, that is their protection." The jury returned a verdict for the defendants.

I have thus presented some of the most troublesome cases coming under my official observation. It is my duty to make as good a diagnosis as circumstances will permit, and advise as to their disposal. The habitual drunkard is often a dilemma with three horns. He may be treated as a pauper, a criminal, or a lunatic. As a pauper he cannot be forced into an almshouse against his will. As a criminal he cannot be tried when delirious, and can only be fined small sums for drunkenness, or committed on the testimony of friends who think him insane. If application be made for his commitment as a lunatic, he stands on his legal rights as a drunkard. The victims of opium eating, though in the same category as the dipsomaniac, can be more easily committed to an asylum, because there is no other legal method of restraint, the opium habit not having yet been made a crime; yet opium eating does not produce that dangerous condition which alcohol does.

The provisions of the English habitual drunkards act are too well known to be again referred to here. That some legal provision is demanded in this State for the proper restraint of habitual drunkards hardly admits of discussion. I will close by quoting again from Balfour Browne, who as a lawyer is not open to the suspicion of a leaning to the medical side of the question. He says,¹ "Looking at the subject from an ordinary common-sense view, we believe that, as in many cases it can be proved that an individual has lost entire control over his actions, in certain relations of which incessant drunkenness is the significant fact, and as to deprive such a person of liberty for a season is to do him no wrong, but rather the compulsory right of making him abstain from what day by day gains an ascendancy over him, and day by day renders ultimate recovery and useful citizenship less and less possible, it is well to resort to restraint in cases in which these facts are capable of being proved." He says,² "It is well known that the law of England has a superstitious respect for the liberty of the subject, and this respect has stood in the way of many most useful reforms." He cites the principle of state education and sanitary reform as examples. He says, "It is calculated that there are about sixty thousand lunatics in England and Scotland, and that there are not less than six hundred thousand habitual drunkards. And it is believed, upon such evidence as can be procured, that not less than fifty or sixty thousand lives are lost annually in England through accidents and diseases caused by the abuse of intoxicating liquors; and yet England will not tie the hands of those suicides, because alcohol is a slow poison." He further remarks, "One thing is certain, and that is that long-continued habits of intemperance, even when they do not induce insanity, almost invariably render the individual incapable of managing his own affairs with any efficiency, and it would seem to be reasonable and in conformity with the expressed opinions of physicians in all countries to restrain individuals thus affected, and in this way give certainty of ultimate recovery. . . . Those persons who shut their eyes to the close connection which exists

between disease and crime are careless observers. Those who, while they legislate for the latter, ignore the existence of the former are careless legislators."

REPORT ON OBSTETRICS.

BY W. L. RICHARDSON, M. D.

THE USE OF TINCTURE OF IODINE IN CASES OF POST-PARTUM HÆMORRHAGE.

DR. W. E. FOREST (New York) gives¹ the account of three cases of post-partum hæmorrhage, which were promptly checked by the use of intra-uterine injections of the tincture of iodine. In two of these all the ordinary means employed in such cases had previously been tried and failed. He believes that the iodine controls the hæmorrhage, not by coagulating the blood as is the case with the solution of the persalts of iron, but by exciting uterine contractions. The blood is subsequently expelled in a liquid form, and thus the danger is avoided of a mass of hard clots being left behind, which is so liable to decompose and thus expose the patient to the danger of puerperal septicæmia. Even when injected in the uterus in its full strength the tincture of iodine has never been known to be followed by any bad results. Its injection into the uterus has never in his practice failed to at once arrest the hæmorrhage. He advises the intra-uterine injection of equal parts of hot water and tincture of iodine, and should there be any signs of a recurrence of the hæmorrhage an injection of the undiluted tincture should be used.

THE OCCURRENCE OF CERTAIN ACUTE DISEASES DURING PREGNANCY.

As regards the relations existing between the puerperal state and typhoid fever, Professor Gusserow contributes² some interesting facts. The occurrence of typhoid fever among pregnant women is comparatively rare. At Basle, among 1420 typhoid patients, only 18 were pregnant. At Vienna, out of 1852 cases, 24 were pregnant. Of the cases at Basle 83 per cent. aborted; while at Vienna only 58 per cent. As to the cause of the abortion no definite reason can be assigned. Professor Gusserow examined a large number of the fetuses obtained from patients who had the fever but was unable to find any pathological changes which were indicative of the fetus having had typhoid fever *in utero*. There seemed, therefore, no doubt but that the high temperature of the mother had a great influence in producing the abortion. From his own observations, confirmed by those of other observers, Professor Gusserow concludes that there can be no doubt but that the life of the child is placed in danger if the maternal temperature exceeds 102° F. The danger is very great if it exceeds 101° F., and the prognosis for the child is fatal if it reach 106° F. The longer the temperature of the mother keeps at a high figure the greater the danger to the child. As a rule, the greatest number of deaths of the fetus occur during the second and third weeks of the fever. It is not, however, necessary for the child to die for an abortion to take place. If the maternal temperature is maintained for several days above 104° F. uterine contractions begin, and the fetus is

expelled. In some few cases Professor Gusserow was unable to trace any direct connection between an elevation of the maternal temperature and the starting up of uterine contractions. In all these cases there was a well-marked chill, followed by a sudden elevation of temperature. As regards the prognosis to be given in cases of an abortion occurring during the course of a typhoid fever, the writer claims that it must depend entirely on the period of pregnancy and of the fever at which it occurs. During the first three months of pregnancy a profuse post-partum hæmorrhage is liable to occur; while during the later months the course of the delivery may be normal. As regards the patient, her chances are better the earlier the abortion occurs during the fever. If it take place at the height of the fever the prognosis is very unfavorable. In all such cases puerperal septicæmia is apt to follow the expulsion of the fetus. Since the great danger to be feared is a marked elevation of the maternal temperature, Professor Gusserow strongly advocates the use of cold baths in all cases of typhoid fever occurring in pregnant women, and he strongly opposes the premature induction of labor with a view either of relieving the mother or saving the child.

As regards the occurrence of measles during pregnancy, Dr. C. E. Underhill considers¹ it a very rare combination, owing probably to the fact that most women are protected by a previous attack during their childhood. When, however, it does occur during pregnancy it must give rise to a very serious prognosis. Measles is most fatal when it comes on soon after the delivery, those women who are confined during the course of the disease standing a much better chance.

Dr. Ringe contributes² a most valuable monograph on the general ætiological relation existing between acute infectious diseases and the occurrence of abortion. He states that pregnancy may be interrupted by any acute disease, but that this is not the usual rule. He agrees with Gusserow that a high maternal temperature (107.5° F. to 108° F.) or even a temperature of 104° F., if long continued, is sure to be fatal to the child. A very important question is whether these diseases may be transmitted from the mother to the child through the placenta. Ringe claims that infection of the fetus from the mother's blood is proved only in cases of variola, although it is very probable that it does occur also in scarlet fever, measles, chicken-pox, and the different forms of malarial fever. He considers, however, that the danger of the death of the fetus being occasioned by direct transmission of the disease from the mother is very slight. As regards the treatment in these cases he advises the employment of every known means to reduce the maternal temperature, the use of stimulants which shall excite the heart to increased action, and thus hasten the circulation, and that such tonics and diet should be given as shall keep the blood of the mother in the very best possible condition.

REST AFTER DELIVERY.

Since Dr. Goodell, of Philadelphia, published a paper strongly advocating the shortening of the period of rest for women after delivery the tendency among the profession has been to follow the practice adopted at the Preston Retreat. Dr. H. J. Garrigues, of New

York, in an excellent article³ on the subject takes the opposite side of the question, and insists upon it that the patient should be kept lying quietly in bed, alternately on her back and sides, until the uterus has contracted sufficiently to be hidden behind the symphysis, and also until all raw surfaces in the generative canal are covered with granulations or healed. Carefully conducted examinations of the uterus made by different observers, all show that the greatest diminution in the size of the womb takes place during the second week after delivery. The puerperal uterus is anteverted and anteфлекed, and, by keeping the woman on her back, the return of the organ to its normal position is best favored. According to Dr. Garrigues it takes about two weeks for the uterus to recede from the anterior wall of the abdomen and to return to the pelvic cavity. In the sitting posture the circulation is more or less impeded, and the process of involution is necessarily retarded. The writer also strongly advocates the use of vaginal injections of a one per-cent. carbolic acid solution twice a day during the process of involution.

ANTISEPTIC TREATMENT OF LABOR.

Professor Stadfeldt (Copenhagen) gives⁴ an account of twelve cases of labor to illustrate the advantages to be derived from the use of disinfecting intra-uterine injections. He also alludes to the results obtained in the Lying-In Institution of the Copenhagen University by the use of these antiseptic precautions. From 1875 to 1879 out of 5098 women confined only 44 died of puerperal septicæmia, or one in 116. He advises the washing out of the vagina before delivery, the delivery of the patient under carbolic spray, and the subsequent use of carbolized intra-uterine injections. He uses the spray the moment the fetus begins to appear at the vulva, and continues it until the labor is over, and any tears which may have been produced are united by suture. The subsequent intra-uterine injections are to be used in large quantities, and the strength should be about three per cent. He does not believe that it is necessary to use these after all cases of labor, but only when the operator has been obliged to use instruments or to introduce his hand within the vulva. They should of course be used whenever a portion of the membranes, however small, has been left behind in the uterus.

Reports of Societies.

PROCEEDINGS OF THE NEW YORK ACADEMY OF MEDICINE AT ITS REGULAR MEETING, DECEMBER 16, 1880.

THE RELATION OF THE OVARIES TO THE BRAIN AND NERVOUS SYSTEM.

At the semi-monthly meeting of the Academy on the 16th of December, Dr. Alexander J. C. Skene, of Brooklyn, professor of diseases of women in the Long Island College Hospital, read a paper with the above title. The various problems connected with this important and interesting subject, he said, he had no hope of solving, but he would at least make some humble efforts to enter upon their investigation and elucidation. In the first place he alluded to the physiological relations of the ovaries to the other sex-

ual organs, and discussed the connection between ovulation and menstruation. The conclusion which he arrived at was that the independence of the two which seemed to have occasionally been observed was the rare exception, and not the rule. "All that we know of the influence of the ovaries in this particular," he said, "points to the probability that these organs are the prime movers in the sexual system." In treating of the regular sequence of actions in this connection, he pointed out certain analogies in the processes of nutrition and the functions of the nervous system.

He then quoted Maudsley on the important influence which the ovaries exerted on the brain and nervous system, and said that with the weight of such authority to support him he was quite ready to agree with Virchow in the statement that it is the ovaries which give to woman her peculiar characteristics of body and mind. There are certain capabilities of the brain which, he believed, were never developed in the absence of the ovaries, and he had himself seen two instances in which, the ovaries being lacking, the women were of a decidedly masculine type. Some authors were opposed to this view. Thus, Goodell had stated that the influence of the ovaries was greatly overestimated. Beyond sterility and the absence of menstruation, he thought that the removal of the ovaries did not render the individual any the less a woman. Peaslee, Battey, and others were of the same opinion. The evidence presented by cases in which Battey's operation had been performed, however, instead of being uniform, varied greatly in different instances. In one case of Dr. Thomas's the sexual feeling, which before had been passive, became aggressive after the operation, while in one of Dr. Pallen's, on the other hand, an excessive sexual excitability and an uncontrollable desire for self-pollution were cured by the operation. In considering the condition of those in whom the ovaries had been removed we should not forget to make certain allowances for the force of habit from long exercise in the system. It was easy for a person who had become blind to talk intelligently of the appearance of surrounding objects, but it was impossible for an individual who had been born blind to form any correct conception of the same. If the uterus and vagina were wanting, and yet the ovaries were present and well developed, the individual would undoubtedly be a perfect woman so far as all the distinctly feminine characteristics were concerned. Perhaps the strongest point in favor of the importance of the office performed by the ovaries was the fact that they sometimes took the place of the uterus, as demonstrated by the phenomena of vicarious menstruation and abdominal gestation.

The emotions depended to a considerable extent on the sexual organs, and the ovaries, on the other hand, were greatly affected by the emotions. Thus, grief, anger, or fear not infrequently arrested menstruation, and, in all probability, ovulation. Again, if the ovaries were imperfectly developed or functionally inactive, the brain and nervous system were not fully and normally developed. In twelve out of sixteen women, whose cases he had studied in an insane asylum, he had found that there was something wrong about the ovaries; and hence he had come to the conclusion that defects in the ovaries were an important element in the causation of insanity, although he did not lose sight of the unquestionable influence of hereditary tendencies also in this connection. In these cases the

mental derangement had made its appearance about the age of puberty, and nutrition had not been materially affected, but still it was possible that the sexual imperfections were merely a part of a general inferior development.

Derangements of menstruation had been justly charged with causing nervous disorders of greater or less severity, but there was much still to be learned in regard to this point. Thus, the subject of ovarian dysmenorrhea was by no means clear. The character and location of the pain seemed to indicate the ovaries as the seat of trouble, the pain being of an aching character, and seldom intermittent. It might precede the menstrual discharge, and generally continued through it and for a short time after its cessation. Pain in the ovaries at the menstrual period, and not at other times, was a recognized condition. The trouble was presumed not to be of an inflammatory nature from the fact that the pain was not constant, and that there was no tenderness of the ovaries on palpation. When the pain preceded the menstrual flow, it was probably connected with the function of ovulation.

Diseases of the ovaries in which there was a neoplastic element did not usually affect the brain or nervous system; and this was, perhaps, because they were, as a rule, unilateral and not accompanied by pain. Inflammatory affections of these organs, on the contrary, had a very marked influence on the nervous system. Dr. Skene said that he had seen all varieties of uterine disease present without producing any such effect; but he had seldom observed any serious disease of the ovaries (other than neoplastic in character) in which this was not involved to a very considerable extent. Ovaritis and displacements of the ovaries were the affections which most frequently caused cerebral and nervous disturbance. In the condition known as ovaritis it had not, indeed, been clearly made out that there was actual inflammation of the organ; but as certain characteristics of the inflammatory process elsewhere were observed, it was advisable to employ the term for the sake of convenience, at all events. When ovaritis was present, pain on defecation, especially if the bowels were at all constipated, was a very common symptom. This pain was of a different character from that due to hemorrhoids or fissure of the anus, and somewhat resembled intestinal colic. In many cases nausea and hysterical symptoms were also produced by the act of defecation, and these were apt to be more marked if the left ovary was the one affected. Prolapse of the ovaries, as a rule, gave rise to the same symptoms. This displacement was generally due to displacement of the uterus; but so long as the ovaries were not tender, and their relations to surrounding organs were not materially altered, the condition might occasion but little trouble. In different cases of prolapse of the ovaries, the amount of suffering experienced varied very greatly, and this, Dr. Skene thought, was due to the difference in the condition of the organs. When there was laceration of the cervix uteri, with eversion, the ovaries were frequently affected, and when a displacement once commenced it was very apt to be progressive.

Pelvic peritonitis accompanied with ovaritis afforded some evidence as to the influence the ovaries exerted upon the nervous system. If there was pelvic peritonitis without ovaritis, there was little or no cerebral or nervous disturbance; but if the ovaries were in-

volved, a marked effect upon the brain was frequently noticed. He had seen four cases of acute mania coming on in the course of pelvic peritonitis, and in three of them had discovered distinct evidence of ovarian disease. When the local trouble had come to an end, the mania and all other mental symptoms completely and finally disappeared. He had also seen two cases of cancer of the uterus in which acute mania had occurred. For a long time there was no mental disturbance whatever; but when, at length, the broad ligaments became affected (and consequently the ovaries), there was much more pain and nervous excitability, and finally mania supervened. In one of these cases he had had the opportunity of making a post-mortem examination, and had found one of the ovaries completely surrounded by cancerous deposit, although it was not determined whether the organ itself was actually the seat of disease. The other ovary it was impossible to distinguish in the disintegrating cancerous mass which occupied the portion of the pelvis in which it would be normally treated. Dr. Noeggerath had found, from a large number of autopsies, that lesions of the ovaries were very frequent; but, unfortunately, we knew comparatively little of diseases of these organs, or how to diagnosticate and treat them.

Dr. Skene then alluded to Charcot's researches in regard to hysterio-epilepsy, and regretted that so unfortunate a term had been chosen to designate the affection, since the uterus was, as a rule, not at all diseased. The condition of the ovaries in such cases was of great importance, but up to the present time was but little understood. The fact that sudden pressure on the ovarian region sometimes arrested the convulsions showed that ovaritis was probably not present. Dr. George Engelmann, of St. Louis, in his paper on hysterio-neuroses, published in the second volume of the transactions of the American Gynecological Society, had presented the most rational discussion of the subject that had yet appeared; but he was not willing to subscribe to Dr. Engelmann's statement that in all these cases there was disease of the uterus. If the uterus and ovaries were both affected, it rendered it more difficult to determine just where the origin of the disease lay.

In any case of cerebral or nervous disturbance it was necessary to determine, *first*, whether the ovaries were affected, and, *second*, how far the affection of the nervous system was dependent on this. The influence of displacements of the ovaries it was easy to make out; but this was not true of other conditions of the organs. The diagnosis of ovarian dysmenorrhœa also was usually not difficult; but to trace such grave disorders as epilepsy and nymphomania to the condition of the ovaries was a very different matter. To do this satisfactorily, and, by removing the ovaries, put an end to the disease, was one of the greatest successes that could crown the gynecological surgeon; but to attribute the affection to the condition of the ovaries, and then, after having removed the organs, find that there was no improvement whatever, was one of the greatest failures that could be met with in the whole domain of medicine and surgery.

The uncertainty in diagnosis which belonged to affections of the ovaries had been fully demonstrated in the various cases in which Battey's operation had been performed. When the symptoms appeared only at the time of menstruation, however, the diagnosis was usually easy. Pelvic pain and tenderness, independent

of the ovaritis, were sometimes mistaken for evidences of ovaritis. These might be due, for instance, to the presence of the remains of old inflammatory processes in the pelvis; and the true diagnosis was sometimes accompanied with very considerable difficulty. In some cases, again, the most serious nervous disturbances seemed to be caused by the pressure of old inflammatory adhesions upon the ovaries, although the organs themselves were free from disease. This was well shown in a case related by Dr. Battey at the late meeting of the American Medical Association, in which he opened the abdomen to perform the operation known by his name, but found the adhesions so numerous and firm that he desisted from removing the ovaries. Afterwards the patient's condition was very materially improved, however, and this would seem to be explained by the fact that during the operation Dr. Battey had broken up the adhesions to such an extent as to remove a great part of the pressure from the ovaries.

It was not necessary to say much on the subject of treatment on the present occasion. It was one in which the gynecologist and the neurologist were equally interested, although the tendency unfortunately was to treat one phase of the trouble exclusively. The great majority of cases required both local and general treatment. For amenorrhœa due to defective ovarian influence the best local treatment (and not infrequently the only one required) was electricity. In ovarian neuroses and congestion and irritation of the ovaries this agent was generally beneficial, but in inflammatory states and displacements its effects were disastrous. Other local measures which might be employed were blisters and the application of iodoform, tincture of iodine, etc. As to general remedies, the bromides were of great service in many cases, and Dr. Skene's custom was to give them in full doses until their constitutional effects were observed; after which he thought it best to give them intermittently and in much smaller doses. Conium was used in the same way. It was a matter of great importance, however, that the patient's strength should be kept up by the administration of suitable tonics at the same time. Opium, chloral, and alcohol often afforded great relief; but of course it was necessary to give them with great caution, on account of the danger of the patient's becoming habitually addicted to their use.

Dr. Skene brought his paper to a close by the narration of a few cases illustrating some of the points touched upon in it. The first was one in which the uterus was rudimentary, but the ovaries perfectly developed, and the sexual characteristics consequently normal. The second was one of dysmenorrhœa, due to diseased ovulation. In the third menstruation was attended with marked and peculiar nervous symptoms, and it was found that the left ovary was enlarged and prolapsed. In the fourth there was prolapse of the ovaries in connection with retroversion of the uterus, and the nervous symptoms which were apparently due to the condition promptly disappeared when it was relieved by local measures, without any resort to constitutional treatment. The fifth case was one of epilepsy associated with inflammation of the ovaries, in which the pain ceased when menstruation commenced.

In the discussion which followed the reading of the paper Dr. Allan McLane Hamilton spoke of organic diseases of the nervous system which he believed originated from diseased conditions of the ovaries, and mentioned particularly the case of a lady whom he had seen with Dr. Mundé, in which there was prolapse of the

ovary associated with epilepsy and attacks of vomiting, and where the result was lateral sclerosis of the spinal cord.

Dr. Mundé, although he agreed, in the main, with all that Dr. Skene had said, thought that the agency of the uterus in causing nervous troubles should not be overlooked. He had frequently seen neurotic symptoms in connection with an enlarged and indurated uterus, where no trouble whatever could be detected in the ovaries, and where these symptoms entirely disappeared after the uterus had been restored to its normal condition. In the course of his remarks he related a case which exhibited the influence of the ovaries upon the nervous system in a very striking manner. A lady who had previously been under treatment for some uterine trouble met with a fall, which produced a displacement of one of her ovaries into Douglas's cul-de-sac; and shortly afterwards she began to suffer pain in the head, and became very irritable, morose, and melancholy, — a state of mind utterly foreign to her natural temperament. When the prolapsed organ was restored, the cephalalgia and mental trouble entirely disappeared.

After remarks by several other gentlemen, Dr. Skene spoke briefly on some of the points brought up, and then, on motion of Dr. J. Foster Jenkins, of Yonkers, it was resolved that a further discussion of the paper should be made the special order for some future meeting of the Academy.

Recent Literature.

On the Construction, Organization, and General Arrangements of Hospitals for the Insane, with some Remarks on Insanity and its Treatment. By THOMAS S. KIRKBRIDE, M. D., LL. D. Philadelphia: J. B. Lippincott & Co. 1880.

This handsomely printed volume is one that will be valued by all persons who are interested in insane hospital management. The author, from his forty years' connection with the Pennsylvania Hospital for the Insane, has acquired a world-wide reputation. Though not a reformer, he has not been slow to appreciate and utilize any new ideas that have had a bearing on the care of the insane. His aim has always been for the best, and he has patiently and unceasingly worked to that end. To Dr. Kirkbride we owe a debt of gratitude, for, while theorists and reformers have been splitting hairs, he has constructed and manned a hospital for four hundred persons, where every appliance that can in any way enhance the true comfort of the patient may be found in constant use. His kindly nature and pure character have done much to elevate the tone of asylum management, and his influence will be felt long after he himself has ceased from active labor.

The first edition of this work was published twenty-six years ago, and since that time the author has found that the correctness of the principles then expressed has been confirmed by the light of subsequent experience. It is not expected that this book will possess any particular novelty to those who have been engaged in the care of the insane for any length of time; it will always, however, prove of great value to those physicians who are just entering on the work, and should be of still greater value to boards of commissioners and others who, entirely without knowledge

of hospital architecture or the needs of the insane, are suddenly thrown into a position where the entire erection of an immense institution is practically left in their hands. These persons can avoid the most lamentable errors by a careful perusal of the book before us.

The book is divided into two parts: Part I. treating of the Construction of Insane Hospitals, and Part II. of their Organization and General Arrangements. The whole book is subdivided into one hundred and nine brief chapters, from half a page, upward. Each one of these deals with some point of interest in hospital construction and management. For instance, in Part I., there are chapters on Water Supply, Drainage, Ventilation, Construction of Cellars, Roofs, Doors, etc. It will not be possible, in this review, to enter into these matters of detail, and we must satisfy ourselves with briefly alluding to a few points of more general interest.

In speaking of the curability of insanity, Dr. Kirkbride states that when this disease is properly and promptly treated, and this treatment persevered in, it may be curable in as many as eighty per cent. of cases. We revere the writer for his cheering hopefulness, so characteristic of him, but regret that we cannot imagine any class of cases where so high a percentage can be hoped for. Under the most favorable conditions we should not look for a higher percentage than fifty.

It is important to place insanity in the same category as other diseases, we are told. "It is just as possible for any one to have an attack of insanity, to recover from it, and to have another attack at a subsequent period of life as it is of any other disease, or as any one is liable to have a first attack. It would be quite as reasonable to say that a patient with fever, rheumatism, or dysentery, or any other attack he may have had in the course of a year, had not recovered from either of them, because from some cause (understood or not, as the case might be) he had suffered from another attack of the same disorder in the same year, as to insist that any one who had had an attack of insanity, and had been relieved of every symptom of it, had not been cured because, at some later period of life, from some cause or other, he had another attack of the same disease." At first sight it seems reasonable to view an attack of insanity in the same light as any other disease; but when we more closely examine the question we find the conditions different. In the words of Dr. D. Hack Tuke, "the relapses after pneumonia and fever, when once cured, would be much less frequent than in mental disease, and the patient himself would be generally a sounder man *physically* in the intervals than the recovered lunatic is *mentally*. Besides, from the different functions of the organs attacked, the permanent consolidation of one lung may allow a man to perform efficiently the duties of his station in life; but the remains of an infinitesimal lesion of the brain may virtually incapacitate him from the performance of his duties in the intervals of his attack." If it were possible to send a patient out of an asylum entirely cured of every symptom of insanity, and after prolonged trial there was no relapse, and if it were further possible for the patient to return to business and manage it successfully for a fair space of time, then we could agree with Dr. Kirkbride that a real cure had been effected. The true state of the case is generally quite different. In the first place, the patient leaves the hospital *before* every symptom of insanity has vanished; and, secondly, it is impossi-

ble to follow him in his future history. As he leaves the hospital, *cured* is entered against his name, and this cure figures in the hospital statistics. It is necessary to draw a line somewhere in settling on the value of recoveries; but it will be more in the true interests of science if the tests applied are more severe in the future than in the past, and the histories of patients after discharge are looked into more rigidly before placing them in the category of recoveries.

Dr. Kirkbride does not favor the home treatment of insanity. It is imperatively necessary that persons should be removed at the first possible moment from home surroundings. The dangers incident to insane persons being at large are much greater than is supposed. Only a few years ago the writer of these pages, by a careful comparison of a list of lives lost and of persons injured by this class of irresponsible people being at large, as reported in the newspapers during a twelvemonth, found that these cases actually exceeded in number all the deaths and injuries from railroad accidents occurring in the United States during the same time."

The number of patients in a hospital should not be greater than the superintendent can visit every day, and even in a state hospital, where fully one half the patients will be chronic and require but little medical care, the number should not exceed two hundred and fifty. The greater the number of acute cases the smaller should be the total number.

In Part II., in speaking of the number of assistant physicians, the writer says that where the number of patients reaches two hundred, especially when there is a large proportion of recent cases, two assistants will be required. This number seems to us a small one; it would be better to say that one hundred patients was a sufficiently large number for one assistant, and a larger number should have the services of two assistants. The routine duties are so numerous, and the service requires such close confinement, that more time for relaxation and study than can now be obtained is imperatively demanded.

It is not desirable, in Dr. Kirkbride's opinion, to appoint a board of consulting physicians. "It is not possible for any one who sees insane patients only at long intervals to prescribe properly for their ever-varying condition, or to judge from short interviews of the real character of their cases." If any disease other than insanity afflicts the patient, then the best of outside medical skill should be freely called in.

The plan of treating the sexes in separate buildings is advocated, as at the Pennsylvania Hospital for the Insane, where there are, as one might say, separate institutions for each sex, a half a mile or more apart. For the first twenty years of the hospital's history the sexes were treated together, for the last twenty separately; the latter arrangement has worked the best. While we can see no particular objection to this plan, neither can we see any advantage to be gained. Taking everything into consideration, we should prefer to treat the two sexes together under one roof. By this arrangement, it is possible for one man to superintend both sexes equally efficiently; whereas if placed in separate buildings at some distance (provided the numbers are large), their care must be left greatly to other persons. It is also a little suggestive of the prison to thus entirely prevent intercourse between the two sexes. We should, on the other hand, prefer to bring them together at balls, tea-parties, and other entertainments, in order to encourage self control and keep alive

an interest in general society. Insanity should no further ostracize a man than, under the circumstances of the case, is absolutely necessary.

In the chapter on the Separation of the Chronic from the Acute Insane, the writer's experience is valuable, as well as timely. It is his opinion that, on the whole, it is better to treat both of these classes together in one institution. If patients cannot be cured they should still be considered under treatment as long as life lasts, for if they cannot be restored to health their comfort and happiness should still be promoted in as far as possible. Almost the same class of means is required for the treatment of the curable and the incurable. We think the following sentence so important that we quote it entire: "When the chronic are in the same institution as the recent cases, there is little danger of their being neglected; but when once consigned to receptacles especially provided for them, all experience leads us to believe that but little time will elapse before they will be found gradually sinking mentally and physically, their care intrusted to persons actuated only by selfish motives, — the grand object being to ascertain at how little cost per week soul and body can be kept together, — and, sooner or later, cruelty, neglect, and suffering are pretty sure to be the results of every such experiment." These words, written upwards of twenty-six years ago, would now be almost of necessity modified by the fact that immense numbers of chronic cases have collected on our hands, filling our hospitals to overflowing and crowding out the acute cases. Our modification would be this: that while the chronic still need medical treatment it differs in certain respects so much from that required for the acute cases that they might be equally well cared for in institutions built peculiarly for them, which, however, should not be mere receptacles, but true hospitals under medical supervision. This is as far as we should go in establishing separate institutions for the chronic insane. Once do away with the hospital plan, once abolish medical supervision, and we take the first step downward toward the poorhouse system, which, in the interest of true humanity, it is our duty to condemn.

In speaking of restraint Dr. Kirkbride thinks that it should seldom be resorted to; but for a limited number of cases its use is sometimes more humane than the hands of attendants. He uses strong wrist-bands, soft leather mittens, and the apparatus for confining a patient to a bed. His experience would indicate that, on an average, not more than one or two per cent. of all patients require any mechanical means of restraint, and often a period of several months may pass without its use in any form.

Report of the Commissioner of Education for 1878. Washington. 1880.

A valuable compilation of facts and figures from all the States, Territories, and cities, from schools of all classes, and from all other institutions of an educational character, with deductions drawn therefrom. It is interesting to note from the report how promptly the school-house follows the railroad and the telegraph, throughout the new regions of the West and South, with its humanizing and civilizing influence. To the account of our home schools are added data regarding education in foreign countries, with a full account of the representation of education in the United States at the Paris International Exposition of 1878.

Medical and Surgical Journal.

THURSDAY, JANUARY 6, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to Houghton, Mifflin and Company, Boston, Mass.

INTRODUCTORY TO 1881.

IN so far as a robust survival of the past twelve months on the part of the JOURNAL is an evidence of the fitness of the form into which it evolved itself on the first of January, 1880, those concerned in the change and in its general management have reason to be satisfied, we will not say elated; for it would have been indeed deplorable had any influences, however adverse, produced an absolutely disastrous effect upon a professional publication so mature and firmly established in its surroundings as the Boston Medical and Surgical Journal. There are doubtless still some of its patrons, and among them perhaps some of those most valued, who regret a break in their bound volumes, and lament the want of proportion between the new volumes and their old book shelves. But even they, we believe, would not have us revert to more contracted dimensions; their grievances are expressed from time to time in a kindly way to steady our equilibrium, and we are sure that the double columns are really no more to them than a trifling blemish engraved on solid and useful qualities.

The enlargement of the JOURNAL was fortunately synchronous with a marked revival of activity and interest in society work, and we may be allowed to think that the two changes act and react in a favorable manner upon each other. It is gratifying to the JOURNAL to feel assured of being able to furnish its readers with so many excellent and valuable papers and discussions upon all the important theories and discoveries of the time; and, on the other hand, it is a proper stimulus and encouragement to members of medical societies to feel that their suggestions and conclusions are promptly brought before a larger audience than that of the society itself. We are led to hope that the revival in this sort of work, which, as far as the JOURNAL is affected thereby, has manifested itself mainly in Boston and its vicinity, will cause itself to be heard from in other parts of New England, and beg to call attention to the appointment on the editorial staff of Dr. F. H. Gerrish, of Portland, Maine. Although recognizing the primary duty of the JOURNAL to continue a faithful expositor of medical thought and events in the part of the country in which it is published, we think the past year has tested and proved its capacity for giving its readers matters of value and interest transpiring in other centres, without neglecting its primitive functions.

Every effort will be made to preserve those features which have been good and acceptable in the past,

and to develop or add to them when prudent and possible.

We are not at all sure of the truth of the physiological dictum that change is life, when applied to the editing of a medical journal. But as time inevitably brings changes in that as in other things we are pleased to have the assurance, which the pages of the first part of this first number give, that an energy hitherto largely drawn upon by editorial supervision has merely transferred itself to the department of original communications; it is not lost, but only gone before.

With well-founded hopes that the JOURNAL and its readers may share in the general good fortune of what promises to be an exceptionally prosperous period, we wish them a Happy New Year.

ADULTERATION OF FOOD.

THE National Board of Trade at their recent meeting received the report of the committee of award, which selected the prize essays on the Adulteration of Food and Drink. The committee recommend a state law which shall be supervised in its execution by a State Board of Health, and that considerable discretion should be left to that board in defining in detail what adulterations are; that there should also be a national law to "deal with adulterated articles coming from foreign countries, or passing from one State into another, and also with adulterations in the Territories, the District of Columbia, and in all places under the special jurisdiction of the United States." A very important part of the report is contained in the little paragraph which says, "Under no circumstances should fees or moieties to informers be allowed."

In consequence of this the committee of award submitted draughts for the basis of a state law, which has not yet been put into a form suitable for use, and for a national law. The latter has been prepared for presentation to Congress, and proposes: (1) the penalty of fifty dollars for transporting, or offering for sale or barter, adulterated articles of food or drugs in places under the jurisdiction of the act; with (2) the addition of a clause to govern the manufacturing of the same within such places; not to allow articles to pass the custom-house if, on examination, they be found to be adulterated. It allows the owner or consignee to have a re-examination made at his own expense, and if the report be favorable to the same the articles shall be returned and passed, but if unfavorable they shall remain in charge of the collector, to be disposed of according to law, with the proviso that the owner or consignee, by paying expenses and giving bond, may re-export them within six months. The National Board of Health is to submit names of qualified persons as special inspectors and public analysts for selection and appointment by the secretary of the treasury at the various ports; and this board is furthermore to prepare instructions governing their work. The National Board is to collect specimens of food and drugs from various parts of the country; to ex-

amine the same, and publish the results of its analyses in the weekly bulletin; the secretary to report in full, and at once, any violations of the act to the proper authority. Then follows a general definition of the adulterations of food or drugs, which makes a drug adulterated "if its strength or purity falls below the professed standard under which it is sold," whether such standard be foreign or that of the United States.

In the case of foods, the National Board of Health may from time to time declare certain exempts and publish a list of the same.

The bill is drawn up with care and completeness as to minor details, involving legal phraseology, and has an additional clause with regard to the mode of prosecution, etc. The modifications and details, of course, it is not necessary to give here.

THE PROPOSED ORGANIZATION OF THE MEDICAL SERVICE OF THE COMPANY CHARGED WITH THE CONSTRUCTION OF THE PANAMA CANAL.¹

At the request of M. de Lesseps, Dr. Louis Campanyo, under the form of a letter to his chief, has drawn up a project for the organization of a medical and sanitary service in connection with the company for the construction of the Panama Canal, in the course of which the peculiar influences to be encountered and the requirements necessary to meet these successfully are pretty carefully and minutely discussed. This memoir was presented to the Academy of Sciences of the French Institute, and was favorably reported on by Baron Sharrey, who recommended it as worthy of the approbation of the Academy. The Institute, it may be mentioned, had previously appointed a committee to take into consideration matters of interest pertaining to the proposed Panama Canal.

Dr. Campanyo had charge of the sanitary and medical arrangements in connection with the construction of the Suez Canal, and to the experiences gained in this undertaking he frequently reverts. These experiences naturally fit him, to a certain extent, for the work in which he is about to engage. A very striking feature of his memoir is his unbounded admiration and veneration for his distinguished chief, which is freely expressed with true Gallic effusiveness. Indeed, there is nothing more characteristic of M. de Lesseps than the contagiousness of his own irrepressible enthusiasm, which seems to communicate itself impartially to all his fellow-workers and subordinates. The views which he professes to entertain as to the present comparative innocuousness of the atmosphere of the Isthmus of Panama, and of the probability that the isthmus will be developed into an actual sanitarium by the cutting of the canal, have been everywhere circulated by the newspapers. This part of the subject was discussed in a pamphlet by Dr. Boyland, of Baltimore, which appeared last summer. Although

due allowances are to be made for the exaggerations of an interested enthusiasm, it must be confessed that a very strong antidote was required to counteract the still more exaggerated and now exploded statement that every sleeper of the Panama railway covered the body of an immolated Chinaman.

If the canal is actually made, it is proposed to do much of the work of excavation by powerful dredging machines, and in so far as possible to employ laborers from neighboring countries and negroes; by such means reducing to a minimum any real dangers from soil and atmosphere of the country itself. To prevent the introduction of epidemic diseases from without, a station of observation at each end of the line is suggested, where all arrivals can be inspected and the suspected quarantined. The line of the works is mapped out in the mind of the future head of the medical service into two divisions of inspection, and each of these into three medical districts, and these, as he naïvely says, only await their names. Each inspection division is to be provided with a hospital, and each medical district with an ambulance service, and in addition there are to be stationary and "flying" ambulances, according to the position of the works. A convalescent hospital is recommended upon an elevated point, and another on the island of Toboga, in the Pacific, a short distance from Panama. The arrangements for the pharmaceutical branch of the service are no less accurately designated, as may be seen from the fact that provision is made for the manufacture and distribution of wine of quinine and aerated waters. A very considerable medical and pharmaceutical *personnel* will, of course, be required, and two midwives are to be on hand. In short, the necessities of the whole service, from the hygienic and medical stand-point, are minutely anticipated, whether in health, in disease, or even after death.

Trees — among others the eucalyptus — and vegetable gardens are to be planted, cattle for slaughtering to be raised, tents and houses to be erected on approved plans, and fire extinguishers to be provided. Libraries, laboratories for chemical analysis and the manufacture of ice, reservoirs for pure water, fish ponds, appliances for baths, douches, and general hydrotherapy are not to be overlooked. Dr. Paquelin's thermo-cautery is to be on hand to deal with the bites of serpents. Heifers or mares *ad hoc* are to be procured to furnish animal vaccine matter. The "social evil" is to be wisely regulated and superintended.

Finally, if, notwithstanding all possible precautions for prophylaxis against the introduction or development of diseases, and all available means for the alleviation and treatment of those who get sick, deaths do occur, as, even in the ordinary course of nature, they must, the service will be equal to the occasion, as several furnaces for cremation are proposed, and in connection therewith, at a given point, a "funerarium," where the ashes of the cremated, inclosed in hermetically sealed vases, will be deposited.

It is plain that any avoidable suffering or mortality among the employees of the Panama Canal Company will not be attributable to a want of foresight and humanity on the part of the president or

¹ *Projet d'Organisation du Service de Santé de la Compagnie du Canal Interocéanique de Panama.*

Lettre à M. le Comte Ferdinand de Lesseps, par le Dr. Louis Campanyo.

Memoire présenté à la Commission de l'Institut du Canal et à l'Institut.

chief medical inspector, but more probably to an insullicieney of funds.

From a more serious point of view, however, Dr. Campanyo's minute and painstaking prevision is very admirable, and worthy of consideration by those who are accustomed to enter upon undertakings in a somewhat more reckless fashion.

KOLPOECPETASIS.

THE above term, which, by way of mitigating the nomenclatural woes of a long-suffering profession, it might perhaps be wished were of somewhat less formidable dimensions, is a new one in medical literature. It is employed by Dr. Nathan Bozeman, of New York, in a paper, entitled *Kolpoecpetasis versus Partial Kolpokleisis*, recently published in Volume IV. of the *Gynæcological Transactions*, in which he gives its derivation from *κόλπος*, vagina, and *ἐκπετάσνυμι*, to stretch out. As the method of vaginal dilatation there described, to which Dr. Bozeman has devoted much thought and study, and which he has now practiced for many years with constantly increasing confidence in its value, is as yet but little understood and appreciated by gynæcologists, and perhaps not at all by the mass of the profession, attention is now called to it in the hope that a more extensive trial of it may be made in appropriate cases, in order that it may be thoroughly tested by competent observers, and the claims of its originator on its behalf either established or disproved.

One of the great advantages which the author claims for this method is that it enables the gynæcologist to do away completely with the operation of kolpokleisis, (complete or partial closure of the vagina), a procedure which, he says, is a "direct acknowledgment of the defectiveness of the resources of gynæcological and surgical art, and when successful proves fatal through the development of uncontrollable sequences in from five to fifteen years." Among these sequences are enumerated vaginitis, endometritis, metritis, ovaritis, cellulitis, peritonitis, cystitis, nephritis, calculi, nervous complications of the severest character, and partial or complete destruction of the sexual and procreative functions. The following eight indications for kolpokleisis were laid down by the late Professor Simon: (1) great loss of substance, making it impossible to bring the two sides of the fistule together; (2) inaccessibility of the fistule, from its high position, from the inversion of its edges, etc.; (3) loss of the infra-vaginal cervix and danger to the peritonæum; (4) hæmorrhage into the bladder, where considerable, after operations; (5) confinement by adhesions of the stump of the cervix uteri inside the bladder; (6) atresia vaginæ above the fistule, with immobility of the posterior border of the latter; (7) obliteration of the urethra, with one fistule below and another above; (8) urethro-vaginal and urethro-uterine fistules.

About the year 1868 Dr. Bozeman came to the conclusion that out of these eight indications for the application of kolpokleisis, in only a single instance

was the operation advisable, namely, loss of tissue, and impossibility, from coexisting adhesion, of bringing the two sides of the fistule together; and since then he has held and successfully demonstrated in his own experience that in every one of these cases his method of gradual preparatory dilatation of the vagina can be resorted to, to the exclusion of kolpokleisis. Notwithstanding that so eminent an authority as Simon had designated the latter as the "most important plastic operation which in the last decennium has originated from one single man," Dr. Bozeman became thoroughly convinced, from the instances of it which he had seen, and especially from a remarkable case of spontaneous kolpokleisis, brought about by inflammatory action, which came under his notice in the year 1870, that the expedient was at most only temporary in its beneficial results, and that, from its liability to be followed in a large proportion of cases by sequences dangerous to life, it ought to be condemned. He was the first to protest against the procedure, and it is a source of gratification to him now to be supported in this matter by Emmet in his work on the diseases of women.

Not only in the various forms of vesico-vaginal fistule, however, is kolpoecpetasis believed to be superior to other methods of procedure, but also in the rarer forms of rectal fistule, as well as in the different varieties of vaginal stenosis and atresia.

The interesting case which forms the basis of Dr. Bozeman's paper was one of vaginal stenosis with recto-utero-vaginal fistule. In it the attempt by an eminent surgeon was first made by partial kolpokleisis to convert the cavity of the uterus and upper part of the vagina into diverticula of the rectum, with the anus serving as a common outlet for the faeces and menstrual blood, while the intercommunicating fistule was left untouched and concealed. But this failed completely, and later the attempt by Dr. Bozeman was made, with entire success, by means of kolpoecpetasis, to reach the intercommunicating fistule by overcoming the stenosis of the vagina, close it, and maintain intact the functions of all the organs involved. The procedure adopted by the first surgeon who operated was an endeavor to unite with the interrupted silver suture the anterior lip of the cervix uteri to the margin of a thick column of cicatricial tissue, the seat of stenosis, which stretched across the rectal wall, just below the cervix and the fistulous opening. If the operation had been successful, the vaginal tract would have been in great part preserved, and the sexual fitness of the organ only slightly interfered with; but, on the other hand, there would have been unnatural menstruation through the rectum, loss of the procreative faculty, and, in all probability, the development of a train of sequences disastrous to health and happiness, and, sooner or later, to life.

By the course of treatment adopted by Dr. Bozeman, however, the fistule was completely cured, and the patient, who had been a fearful sufferer for many years, restored to perfect health. The author holds, therefore, that his method of procedure occupies a higher sphere than others, on account of its greater

applicability, and he has found by experience that when others have been tried, and (even under the most advantageous circumstances as regards the skill of the operator, etc.) have failed, his plan can be resorted to just as readily and successfully as though no such attempt had ever been made.

Just what, then, is the method of kolpoeptetasis which the author advocates so strongly? In the case of vaginal stenosis with recto-utero-vaginal fistule above alluded to, Dr. Bozeman thus describes the measures adopted: "Two or three days after my first examination the patient, by the aid of one assistant, was confined in the knee-chest position upon my supporting chair, anesthetized, and operated upon as above indicated. The thick column of cicatricial tissue, projecting forward from the rectal wall, was divided backwards at three points. This being completed, intra-vaginal dilatation with cylinders of compressed sponge in oil-silk bags was commenced and gradually increased, with further incisions, as were from time to time required, until the point of resiliency in the stenosis had been entirely overcome, and the fistule brought fairly within reach of operative procedure. This preparatory step of the treatment, thus commenced and carried out, required about six weeks, when the final step for closure of the fistule was undertaken." The following is a more detailed description of the method, by Dr. Ludwig Bandl, clinical assistant and lecturer on obstetrics and gynecology in the University of Vienna, who for three months had the opportunity of observing Dr. Bozeman's hospital practice in that city:—

"The beginning of the procedure is to pay attention to excoriations and abrasions of the vagina and of the external genital organs. He cuts off the hair found in the posterior vaginal angle, which is usually incrustated with deposits of urinary salts, greatly irritating the excoriated surfaces and causing great distress to the patient. After this is carefully done, a solution of argenti nitratis (one drachm to one ounce of water) is applied to all the abraded points inside and outside the vagina. By these means the woman is freed from pain, and soon her confidence is gained; which is absolutely necessary, especially if the treatment is to be protracted. At the same time, during the first examination, cicatricial bands are divided, and the vagina dilated as far as possible with the fingers. After this, dilators of gradually increased size are kept constantly in the vagina. The latter consist of balls and cylinders of hard rubber (or other unyielding material). Both balls and cylinders are perforated near the surface or end, and a string is passed through and tied in a loop to facilitate removal from the vagina. According to the vaginal dimensions, therefore, a cylinder is inserted and allowed to remain from ten to twelve hours. It is then withdrawn, and the vagina flushed thoroughly with tepid or cold water; or the woman is placed in a hip-bath to recover from this first proceeding. Already after three or four days one is surprised at the effect produced by this treatment; the hard dilator, firmly encircled everywhere by the surrounding walls of the vagina, softens the tissues; cicatricial

bands, heretofore unperceived, are recognized; and last, but not least, the bladder, which had previously projected outside the vulva, in consequence of the great deficiency existing in the posterior vesical wall, is now found to have resumed its proper place when the patient is placed in the knee-elbow position. Superficial incisions are afterwards made whenever any resistance is found in the vagina and is likely to cause obstruction, and a dilator of larger size, either ball or cylinder, is introduced. The woman soon becomes accustomed to this procedure; she now bears it gladly, for she is enabled to remain in bed for hours in a dry condition. While thus treated she can easily attend to her household duties, if she chooses, and also can enjoy comfortable nights. After this course has been persisted in for from three to five days, or even a longer time, the vagina, previously hardened and stiffened by cicatricial tissue, becomes soft and enlarged, while the edges of the fistule are clearly visible."

(To be concluded.)

MEDICAL NOTES.

— General Albert J. Myer — better known as "Old Prob" — was a graduate of the Buffalo Medical College.

— An ovarian tumor weighing 125 pounds was removed lately at the Carney Hospital by Dr. John Homans.

— We take especial pleasure in seeing the pages of the *JOURNAL* copied by other medical periodicals; but the pleasure is somewhat marred when the copying journal fails to acknowledge the source from which it draws. The *Atlanta Medical and Surgical Journal* for December, 1880, fills eight pages at our expense without signifying its indebtedness.

— Dr. Buckminster Brown has felt himself obliged, by failing health, to surrender his active duties at the Good Samaritan; but as consulting surgeon will continue to give his services to the institution with which he has been so long connected.

— Dr. Edward H. Bradford has been appointed surgeon to out-patients at the Boston City Hospital in place of Dr. Thomas Dwight, resigned.

— Dr. C. A. Walker has resigned the superintendency of the South Boston Lunatic Asylum, and Dr. Theodore W. Fisher has been appointed his successor.

— A Holstein peasant, says *Public Opinion*, unimpaired in microscopic research, and not possessing the requisite instruments of precision, has devised for himself a new test for the presence of trichinae in pork. When he killed a pig he was careful to send a portion of it—a ham or a sausage—to his pastor, and then waited the consequences for fourteen days. If his pastor remained healthy, then he felt perfectly easy in his mind, and well assured that his pig fulfilled the requisite conditions of soundness of food, and he proceeded to dispose of it accordingly in his own family. This ingenious method of research has not been considered satisfactory by the district physician.

—We received notice from the *Allgemeine Wiener Medizinische Zeitung* of the celebration last month of its twenty-fifth anniversary. Dr. B. Kraus has been its editor during the whole of this long period, and we take especial pleasure in tendering him our congratulations on the completion of a quarter of a century in the editorial chair, and on the high standing of his periodical.

Miscellany.

FEIGNED EPILEPSY.¹

CASE OF JAMES CLEGG, THE "DUMMY CHUCKER."

AFTER his discharge from this prison Clegg returned to his native city, immediately robbed his aunt, fled to London, thence to Glasgow, where he robbed a house of four hundred pounds, and then sailed for America. Landing in New York he recommenced dummy chucking, which, he says, was something new to the "crooked people" of that city. He joined a gang of pickpockets, and operated in New York, Philadelphia, and Boston. Large retail houses afforded a rich field, lady customers being especially victims during their consternation at sight of a well-dressed young man writhing on the floor. The ferry-boats, when crowded, offered excellent opportunities. On one of these occasions a kind-hearted physician came to his assistance, and *meanwhile was relieved of his watch*. Unaware of this, the doctor, on landing, called a cab and took the scamp to his own office, where, after considerable effort, he succeeded in "restoring" the patient, about the same time discovering the loss of his watch. Clegg expressed great sorrow, and denounced the outrage, but the doctor consoled himself by the reflection that the loss of the watch was of little consequence compared with the life he had been instrumental in saving. Clegg admits that for once his conscience smote him, and avers that he really tried to get the watch for the purpose of restoring it to its owner, but it was "sold" before he got back to the city again. On another occasion he feigned a fit on a Fulton ferry-boat, and was taken in an ambulance to Bellevue Hospital. After pretending to sleep for an hour or two at the hospital he "recovered;" but the authorities were suspicious, and detained him, as the nurse informed him, for the purpose of having him examined by one of the physicians of the Hospital for Epileptics. In due time the physician from the epileptic hospital arrived, and Clegg, who was on the alert, hearing the nurse say, "There comes the doctor," feigned a fit, and was in "convulsions" when the latter reached his bedside. The doctor, after watching him a few moments, depressing his eyelids, trying his pulse, and observing the numerous cicatrices on his face and forehead, expressed the opinion that it was a case of epilepsy, and Clegg was discharged.

Subsequently he was sent to Blackwell's Island Prison for stabbing a man. Here the chief of staff of Charity Hospital pronounced him an epileptic. His next commitment placed Clegg in Sing Sing Prison. Here his "dummy chucking" became the means of his transfer to the Asylum for Insane Criminals at Auburn. At this place Dr. MacDonald, on assuming charge, found Clegg in a strong room and in restraint.

He was said to be "subject to terrible fits." Dr. MacDonald ordered his release from restraint, requesting notification should a fit occur. Shortly after he was called. He found Clegg on the floor, his face distorted and livid, saliva, frothy and bloody, oozing from the mouth; body apparently violently convulsed. Two patients were holding his limbs. He seemed to be having a series of rapidly recurring convulsions, each one commencing with marked muscular rigidity, the head being drawn to one side, the body twisted upon itself. Thoracic muscles rigid, respiratory movement almost completely arrested. This tetanoid condition was quickly followed by one closely resembling clonic convulsions: there were alternate contractions and relaxations of different portions of the body, during which his head was frequently brought into such violent contact with the floor as to abrade the scalp; his tongue was wounded; respiration jerking and noisy, and at each expiration bloody saliva was forcibly ejected from his mouth. Pulse somewhat accelerated; eyes turned upward as far as possible; pupils moderately dilated. (It should be stated that the room was partially darkened by a window screen, kept locked. This would account for the dilatation of the pupils.) "His hands were tightly clenched, but I observed that the thumbs were not closed within the hands," also that *the finger nails were not livid, and when I forced his hands open he immediately closed them again.*² *There were also no visible indications of relaxed sphincters.* The 'clonic convulsions' were followed by a condition of muscular quiet, immobility, and stupor, lasting for a few moments, during which he would occasionally open his eyes and gaze around in a confused and stupid manner,³ when, suddenly, another 'spasm' would supervene. The series of seizures lasted about an hour, followed by a pretended sleep, after which Clegg appeared to be mentally confused for a day or two, and complained of headache and physical weakness."

On this occasion Dr. MacDonald intimated, in Clegg's hearing, that he was an impostor, although he confesses he was not positive at the time, but deemed it safe to assume from his history that the rogue was shamming. Attendants were instructed to impress upon his mind that the doctors regarded him as a fraud. The next time Dr. MacDonald met Clegg he accused him of feigning. The man stoutly denied it, calling attention to the scars on his head and face, asking if the doctor thought he would purposely hurt himself like that, and adding that he had been subject to fits since he was three years old. The doctor's suspicions were again awakened by the next fit, which began *soon after he entered the ward*. He again said the fellow was shamming, and that, while his acting resembled epilepsy, it lacked certain characteristic features, the absence of which stamped it as counter-

¹ "They [epileptics] clasp the thumb upon the palm, and hold it down with giant-like force." (Radcliffe, *Epilepsy and other Convulsive Affections*.)

² *Dictionnaire des Sciences médicales*, vol. xiii, p. 542 (Marc). "Ordinarily the fits (*poignets*) are spasmodically closed in epilepsy, and are opened with much difficulty, but when once opened they remain so to the end of the fit, or they are only reclosed when there follows an exacerbation of the spasm. The fits of a feigning epileptic are not only opened with less effort, but the impostor thinks he is acting well his part in immediately reclosing them."

³ "If an impostor is narrowly watched, he will be found to open his eyes occasionally, for the purpose of observing what effect his acting produces upon the by-standers. This led to the detection of a man who twice simulated a paroxysm so successfully as thereby to evade punishment, and very nearly succeeded a third time." (Marshall, *On the Enlisting of Soldiers*.)

feit. Clegg subsequently told the doctor that this announcement staggered him. "For," said he, "I have studied the subject in books, have seen a great many epileptics in fits, and have practiced it for fifteen years, until I thought I knew every symptom of it." After he had recovered from this "attack" the doctor watched him on occasions when Clegg was unaware of his presence, and was struck with the cheerful and vivacious aspect of the man's countenance, as compared with his facial expression during the ward visits. Clegg could easily assume the peculiar, indescribable look habitual to epileptics. This, together with the cicatrices on head and face, might easily deceive even a skilled observer.

By this time Dr. MacDonald felt justified in insisting upon a confession from Clegg, who still denied feigning, but with less emphasis, until the doctor forcing him still more, he laughingly admitted that the fits were simulated, but mildly urged that he was a victim of *real* epilepsy. This Dr. MacDonald refused to admit, and threatened him with unsparing punishment in the event of another "fit." After brief reflection Clegg said, "Well, I guess it's no use, but you are the first doctor that ever tumbled to me." His countenance then underwent a decided transformation, the epileptic look vanishing at once. He was transferred to Auburn Prison as *not insane*, and was released in December, 1876. He next went to Boston, where he resumed the practice of "dummy chucking" in connection with a gang of pickpockets, and afterwards followed the Marquis of Lorne to Canada, chucking dummies in the crowds that gathered. Returning to New York, he was sent to Sing Sing for burglary, and there played epilepsy, which again sent him to the Auburn Asylum as an "epileptic imbecile." Meeting Dr. MacDonald in the ward, he threw off his epileptic mask, laughing heartily. On this occasion, at the request of the doctor, he feigned a fit, first borrowing a pocket-knife, with which he calmly cut the side of his tongue; then, uttering the "epileptic cry," fell violently upon the floor in a "convulsion." He afterward repeated the fit in the presence of two other physicians.

Dr. MacDonald says authorities are divided as to whether it be easy or difficult to feign epilepsy. Gavin, Van Swieten, and De Haen report cases in which impostors suffered the most flagrant liberties and allowed pins and needles to be thrust into their bodies without betraying consciousness.

Clegg made a practice, while in prison, of complaining of vertigo, tinnitus aurium, etc., between the paroxysms. When asked what remedy he had taken he always replied, "Bromide," knowing that was "the medicine the doctors give for epilepsy." Realizing that if he fell in such a manner as to avoid injury suspicion would be aroused, he never selected a "soft place" on which to fall. Reynolds¹ remarks that "choice of locality (for falling) does not prove that epilepsy is feigned; the absence of choice, on the other hand, is presumptive evidence that it is genuine; and this in proportion to the danger or the privacy of the locality in which the fall occurs."²

"Cicatrices on the skin of the face," says Gavin, "made with the design of presenting incontestable proofs of anterior falls, never exist without tending to deceive the medical man." Clegg sets a high value

upon the scars upon his head and face, acquired through falls. He says they have often served as aids in diagnosis to examiners who have pronounced him "an epileptic."³

"In conclusion," says Dr. MacDonald, "these are the grounds upon which the opinion that Clegg was not an epileptic was based: First, he was a convict, sentenced to hard labor,—this furnished a strong motive for feigning, and suggested suspicion; second, the occurrence of a paroxysm during my visit to the ward; third, the readiness with which he spoke of his complaint, and called attention to the cicatrices on his face and head; fourth, the marked change in his facial expression when he supposed he was unobserved; fifth, during the spasms the thumbs were not closed within the palms, the nails were not livid, muscular rigidity could readily be overcome, and the hands, after being forced open, immediately closed; sixth, the sphincters were not relaxed; and, seventh, there were no ecchymoses, extravasations, or minute petechial spots observable upon forehead, throat, or chest. The presence or absence of pallor was not determined by observation in Clegg's case, nor was any value attached to the condition of the pupils.

"As regards the question of pallor, Dr. MacDonald agrees with those who maintain that it is not a constant symptom attending the onset of epileptic seizures. Reynolds speaks confidently of its absence in some instances. In a total of forty-five observations recorded by him, 'pallor was observed in but little more than one fourth of the cases.' Owing to its exceedingly evanescent character, its presence can be determined only in cases observed from the very commencement of the attack. My experience leads me to conclude that, as a rule, in general practice, persons suffering from epileptic attacks do not come under medical observation until the 'pallid stage' has passed. Of course it cannot be feigned; and while its recognition might warrant the dismissal of suspicion of shamming in a doubtful or suspected case, its absence in a given case would by no means justify a verdict of feigning.

"Respecting the condition of the pupils during an epileptic attack authorities are also divided, some claiming that the iris expands, a few that it contracts, while others declare that it oscillates. *The important point relating to the condition of the pupils in epilepsy, as regards its diagnostic value, is that during a paroxysm they are insusceptible to the influence of light.* This fact would be of great service as a means of diagnosis of feigned epilepsy, but for the difficulty of determining its presence or otherwise in a person violently convulsed."

Dr. Landon Carter Gray, in a communication to the *American Journal of the Medical Sciences* says: "If there be any one phenomenon which is constantly or generally present in true functional epilepsy, and not in that which is due to organic disease, it has seemed to me that such a phenomenon would do considerable service to the clinician. Such a symptom, if my observations be trustworthy, is a dilated and mobile pupil. *By this I mean a pupil which changes from contraction in a bright light to dilation in a shaded light much more quickly than the normal pupil, some-*

¹ *Epilepsy, its Symptoms and Treatment*, page 285.

² Portal, *Sur la Nature et le Traitement de l'Epilepsie*, page 127.

³ Fallois relates a case where "the limbs were covered with the marks of contusions of different dates, as evidenced by the differences of coloration," and where, "the night after admission, the impostor wounded his forehead and nose."

times instantaneously, undergoing the changes from dilatation to contraction with the same facility, and which is, moreover, moderately dilated even in a bright light. The mobility and dilatation were usually in proportion to the inveteracy and violence of the disease, although not always so. The cases of *petit mal* have exhibited this phenomenon in a marked degree."

THE TREATMENT OF DRUNKARDS BY THE STATE.

THE *Northwestern Law Reporter* sketches desired legislation as follows: "Legislature is asked to place dipsomaniacs—persons whom the use of alcohol, or other intoxicants, has rendered mentally incapable of performing the duties required of a member of society, or of providing for a family, or who, from their use, have become a burden or a danger—on the same legal basis status as other lunatics, and to extend the authority to place them under restraint and supervision

for a lengthened period of time, on the ground that they are persons of unsound minds. Such restraints shall be in appropriate buildings, to be called inebriate hospitals,—which shall be branches of the insane hospitals,—where they shall receive such proper medical and special treatment as is required for the restoration of persons of unsound mind to a condition of sanity. This treatment shall be extended over such a period of time as to insure the permanence of the cure, in case such may be found possible. Should the best directed efforts of their medical attendants show the fact that any cases are incurable, such cases shall be transferred for restraint and protection to appropriate buildings, to be called inebriate asylums, which shall be branches of the authorized insane asylums for the incurably insane. That in the asylum they be encouraged and required to contribute from their skilled labor, manual or intellectual, to the payment of the expense of the State for their support, even in cases in which they or their relatives may be able or willing to pay for their maintenance."

Deaths reported 2598; 947 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 562, lung diseases 395, consumption 393, diphtheria and croup 282, scarlet fever 93, small-pox 47, typhoid fever 36, diarrhoeal diseases 25, malarial fevers 20, cerebro-spinal meningitis 18, whooping-cough 14, erysipelas 14, measles 13. From

typhoid fever, Philadelphia seven, Chicago six, Cincinnati five, Baltimore four, Buffalo three, Boston and Pittsburgh two, New York, Brooklyn, District of Columbia, Nashville, Fall River, Salem, and Taunton one. From diarrhoeal diseases, Cincinnati six, New Orleans five, New York, Brooklyn, and Baltimore three, Chicago, St. Louis, Boston, Charleston, and Brooklyn one. From malarial fevers, Brooklyn seven, New York

five, New Orleans three, Charleston two, Chicago, District of Columbia, and Lynn one. From *cerebro-spinal meningitis*, New York and Worcester four, Chicago three, Philadelphia two, St. Louis, New Orleans, Milwaukee, Fall River, and Springfield one. From *whooping-cough*, Baltimore five, New York three, Philadelphia, Brooklyn, New Orleans, Providence, Worcester, and Cambridge one. From *eczema*, New York and Brooklyn three, Baltimore two, Philadelphia, Chicago, Boston, Cincinnati, Milwaukee, and Cambridge one. From *measles*, Boston nine, New York two, Chicago and St. Louis one.

One hundred cases of diphtheria, 95 of scarlet fever, measles six, typhoid fever three, whooping-cough one, small-pox one, were reported in Brooklyn; diphtheria 46, scarlet fever 10, in Boston; scarlet fever 41, diphtheria 15, in Milwaukee; scarlet fever 12, diphtheria 11, typhoid fever three, measles one, in Providence; diphtheria nine, typhoid fever two, in Somerville; small-pox one, in Holyoke.

In 39 cities and towns of Massachusetts, with a population of 1,042,531 (population of the State 1,783,086), the total death-rate for the week was 20.86, against 21.32 and 20.43 for the previous two weeks.

For the week ending December 4th, in 150 German cities and towns, with an estimated population of 7,713,385, the death-rate was 22.8. Deaths reported 3334; 1537 under five; pulmonary consumption 449, acute diseases of the respiratory organs 287, diphtheria and croup 156, typhoid fever 98, scarlet fever 73, measles and röteln 66, whooping-cough 50, puerperal fever 15, small-pox (Königsberg) three. The death-rates ranged from 8.3 in Carlsruhe to 29.5 in Chemnitz; Königsberg 25.7; Breslau 29.2; Munich 21.6; Dresden 21.3; Berlin 26; Leipzig 22.4; Hamburg 23.5; Hanover 18.1; Bremen 21.5; Cologne 25; Frankfurt 19.6; Strasburg 27.2.

In the 20 chief towns in Switzerland for the weeks ending December 4th and December 11th, population 522,856, there were respectively 32 and 29 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 14 and 17, diphtheria and croup five and 12, small-pox four and six, typhoid fever four and five, whooping-cough two and three, measles one and two, scarlet fever none and one.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

CORRECTION.

MR. EDITOR, — I have just had sent me the Boston Medical and Surgical Journal for December 16th, in which is a report of my remarks at a meeting of the Association for the Protection of the Insane, held in New York, November 11th.

In one or two matters the report quite misrepresents what I said, but no one will be injured thereby. I spoke of neglect and abuse as the proper term to apply to the manner of treatment of some state insane, not the majority of them. Nor did I refer to "even the best institutions" in the language put in my mouth. And in referring to the Scotch asylums I simply quoted from the lunacy reports relating to the Fife and Kinross asylum, and also from Dr. Luke's report of last summer.

I am sure that many of our public asylums are improving, both in the matter of occupation and restraint, and I may add freedom. Dr. Kirkbride, in his new book on Insane Asylums, almost surrenders on the question of restraint. Yours very truly,

H. B. WILBUR.

SYRACUSE, N. Y., December 20th.

DAVID P. SMITH, M. D.

At a special meeting of the Hampden District Medical Society, held December 28, 1880, the death of Dr. David P. Smith, late Vice-president of the parent society, was announced, and a committee was appointed to draught resolutions commemorative of the sad event.

Whereas, It has pleased our Heavenly Father to remove from us, by death, our esteemed friend, valuable associate, and fellow member, Dr. David P. Smith,

Resolved, That we desire as individuals and as a society to place on record our appreciation of the life and character of our deceased brother; that we call to mind with gratitude his distinguished services to the profession and community, his labors as a member and officer of our association, and our regret at his sudden and untimely death.

Resolved, That our heartfelt sympathy is hereby tendered to the bereaved wife and brother, and that we condole with them in this their sad hour of sorrow and affliction.

Resolved, That we attend the funeral in a body; that these resolutions be spread upon the minutes, and a copy of the same be sent to the wife of our deceased member; and also that they be published in the *Springfield Republican* and Boston Medical and Surgical Journal.

THE AVERAGE DAILY AMOUNT OF URINE:
ITS IMPORTANCE IN DIAGNOSIS.¹

BY E. S. WOOD, M. D.

THE importance of the daily measurement of the amount of urine in disease, although referred to in all works upon the examination of the urine, is not so fully appreciated as it should be, and the neglect of this simple aid to diagnosis may in some cases result in serious error. The examination of the urine is, in the vast majority of cases, resorted to for the purpose of ascertaining the presence or absence of the more serious forms of renal disease, and, if one or more of these exist, to determine its nature; and it is in just those cases, in which it is desirable to eliminate the existence of organic renal disease, that the knowledge of the amount of the urine is of the greatest importance.

It is true that in many cases the diagnosis of serious renal disease can be made with certainty by the other characteristics of the urine, but there are some in which very great assistance is obtained by simple measurement. This is naturally of the greatest consequence in those cases in which a quantitative estimation of the solids is also required. It is not possible in many cases to ascertain, even approximately, how much work the kidneys are capable of doing without knowing approximately the average amount of urine which those kidneys are eliminating, and it is self-evident that the kidneys cannot be suffering from very advanced degeneration, and yet be doing a normal amount of work.

It is only in an exceedingly small percentage of the cases in which I examine the urine, that I am able to learn approximately how much the patient is passing. Even in our hospitals with skilled attendants it is only in the ward specially assigned to nervous and renal diseases at the Boston City Hospital that the practice of daily measuring the amount of urine of the patients is habitual. In private practice, measurement of the urine, in cases of known or suspected renal disease or complication is the rare exception. Most frequently the medical attendant relies upon the statement of the patient or nurse that a larger or smaller amount than usual is being passed; yet it is well known that patients are very frequently deceived in this respect, thinking that they are passing more urine than usual on account, perhaps, of frequent micturition, when actual measurement shows a diminished amount.

It is no hardship to require actual measurement of the urine even in the case of patients who are not confined to the house, since they can be provided with a wide-mouthed bottle fitted with a tight stopper, and sufficiently large to contain the amount passed at a single micturition. This bottle can be graduated into twenty-five or fifty cub. cent. spaces, or into fluid ounces, by a file-mark on the glass, or by marks on a strip of paper pasted on the outside. This may, if necessary, be carried in the pocket, and the amounts passed at each micturition be noted.

It is only after knowing the actual amount of urine in the twenty-four hours that we have the starting-point for ascertaining the rapidity of the metamorphosis going on within the body and the amount of work

being done by the kidneys; the estimation of the total solids, which is, to a certain extent, the measure of the metamorphosis, is easily made approximately by multiplying the last two figures of the specific gravity by 2 $\frac{1}{2}$, which gives the number of grams of solid matter in one liter of urine; and from this, knowing the amount of urine, the daily amount of solids eliminated by the kidneys is readily calculated.

Without desiring in the least to undervalue the quantitative estimation of the more important urinary constituents, I wish to lay stress upon the fact that with these two pieces of information, the average amount of urine and the specific gravity, together with the ordinary clinical examination of the urine, we have the data for preventing many errors in diagnosis, and consequent errors in prognosis, which might otherwise be made.

In this paper I shall not consider the amount of urine in general diseases, such as the average diminution in fevers or the great increase in diabetes, but shall limit myself to the consideration of those cases which are liable, on account of temporary albuminuria, or for other reasons, to be confounded with organic disease of the kidney. For the purpose of comparison I will first briefly mention the average amount of urine eliminated in the various forms of Bright's disease, and will illustrate by a few cases, for most of which I am indebted to the records of the Boston City Hospital.

In acute parenchymatous nephritis the amount is at first much diminished, and then gradually increases with the diminution of the inflammation up to the normal amount; with convalescence it exceeds the normal considerably; and finally, in those cases which terminate in recovery, with complete restoration of the kidney to a healthy condition, it falls again to the normal.

Examples: (1.) J. H. entered the hospital after being ill two weeks. The amount of urine was then 473 cub. cent.; during the next ten days, with the diminution of the dropsy, the amount gradually rose to 1626 cub. cent.; with convalescence, it averaged for eighteen days 2410 cub. cent.; and finally fell, with the restoration of health, to the normal. (2.) J. A. passed during twenty-four days before death, on the average, 496.5 cub. cent. The autopsy showed simple acute nephritis. (3.) In another fatal case the average of twenty-nine daily measurements before death was 1234 cub. cent. (4.) In another case, three weeks after the beginning of the illness, the amount was 1300 cub. cent.; it then gradually rose to 4022 cub. cent.; and finally fell to the normal as health became reëstablished.

In chronic parenchymatous nephritis the amount of urine is always below the normal. Possibly for one or two days the amount may exceed the normal by one or two hundred cub. cent., but this increase is very rare and only temporary. With the increase of the disease, accompanied by increasing dropsy, the amount is very small and the urine concentrated, but when the progression is not active, the amount is but little below the normal.

Examples: (1.) In the case of J. G. the average of sixty measurements was 1239.5 cub. cent. There was frequent micturition (three or four times during the night), when only from 500 to 1000 cub. cent. was being passed. (2.) In the case of A. W. the average of 171 daily measurements was 1005 cub. cent. (3.) In the case of J. S. the average of twenty-three meas-

¹ Read before the Boston Society for Medical Improvement, December 27, 1880.

urements before death was 658 cub. cent. (4.) In another case (M. P.) the average of eighty-two measurements, the last one being a few days before death, was 965.5 cub. cent. On only one day did the amount exceed the normal (1774 cub. cent.).

In both interstitial nephritis and amyloid degeneration the amount of urine is largely increased, even to three or four times the normal amount, except during a short time previous to death, when the quantity may be less than normal.

Examples: (1.) In one case the average of twenty-five measurements in May and June was 2288 cub. cent. Death took place in August, and the autopsy showed interstitial nephritis. (2.) In the case of J. C. (interstitial) ninety-five daily measurements gave an average of 2266 cub. cent. (3.) In the case of J. M. (interstitial) the average of forty-one measurements just before death was 1017 cub. cent. (4.) In the case of K. G. (amyloid) fourteen measurements during the month before death gave 921 cub. cent.

In complicated cases, which are far more common than uncomplicated ones, the amount of urine varies according to the nature and extent of the complicating affection. A very frequent combination is that of amyloid degeneration and chronic parenchymatous nephritis, or interstitial and chronic parenchymatous nephritis. Acute parenchymatous nephritis is liable to occur with any of the other renal diseases, as a result of exposure or from other cause. The result of the admixture of chronic or acute parenchymatous nephritis with either the interstitial or amyloid degeneration is to diminish the amount of urine, and the amount of this diminution is, of course, dependent upon the extent of the parenchymatous complication, as the following cases show:

Examples: (1.) G. C. passed, during twenty-eight days, an average of 563 cub. cent. During this time the abdomen was tapped several times. Death occurred about three months after the last measurement, when the kidneys were found about one half of the normal size, and both "fatty and amyloid." (2.) T. D. passed, on the average, during forty-three days before death, 2198.5 cub. cent.; or, omitting the last eight measurements, when the patient was moribund, which were, respectively, 532, 0, 0, 177, 7, 14, 118, and 177 cub. cent. (average = 128 cub. cent.), the average of the previous thirty-five days was 2671.5 cub. cent. After death the kidneys were found to be in a state of amyloid degeneration and chronic parenchymatous nephritis.

If a parenchymatous affection exists as a complication of either an interstitial nephritis or an amyloid degeneration, it is almost sure to be detected by the increased amount of albumen and the character of the sediment; the measurement of the amount of urine is often in these cases of especial importance in making a diagnosis of such complications. If, for example, we have a specimen of urine with hyaline, granular, and fatty casts, and fatty renal epithelium in the sediment, and at the same time the urine contains a considerable amount of albumen, it is impossible for us to say, without knowing the average amount of urine, whether we are dealing with a case of pure chronic parenchymatous nephritis, or one of the other forms of Bright's disease in which the parenchymatous affection is merely a complication; but if, as in the case of T. D., mentioned above, we knew that the daily amount of urine averaged between 2000 and 3000 cub. cent., we might be reasonably sure that the parenchymatous disease

was not the principal one, but only a complication. If the parenchymatous affection is the principal one, the amount of urine will be diminished, in which case it is impossible without the history of the case to determine the existence of any of the other forms of organic renal disease, as in the case of G. C.

It is well known that Bright's disease is diagnosed chiefly by the detection of albumen in the urine and renal casts in the urinary sediment, and I frequently meet with physicians at the present time who pronounce the existence of serious organic renal disease from these characteristics alone, which may occur without any serious disease of the kidneys. Daily measurement of the urine in these cases is of very great assistance. In hyperæmia of the kidneys, for instance, due to disease or abnormal condition of some other organ, we frequently find both albumen and casts, and a knowledge of the amount of urine may prevent an error in diagnosis and prognosis.

In passive hyperæmia of the kidneys, due to cardiac or other disease, we find in the urine, so far as the kidneys are concerned, only hyaline and finely granular casts and a trace of albumen,—conditions which are only found in the interstitial and amyloid forms of Bright's disease; but the average daily amount of urine in passive hyperæmia is diminished, while in the above-mentioned organic diseases it is much increased.

In active hyperæmia of the kidneys, due to the elimination of some virus or drug, the amount of urine is usually diminished, owing to the febrile complication, and in addition to the sediment mentioned above in cases of passive hyperæmia, we find free blood and renal epithelium and usually an occasional blood and epithelial cast; albumen is present only in mere traces. These characteristics of the urine and sediment are the same as those of acute nephritis, but in the proportion in which they occur in the stage of convalescence, when in acute nephritis the amount of urine is increased, and often much increased, while in this condition of hyperæmia it is almost always diminished.

Examples: (1.) In the case of W. K. the average of seventeen measurements during two months was 622 cub. cent. The urine at first contained no albumen, but a few hyaline casts; later a trace of albumen with hyaline and an occasional epithelial cast, with considerable free renal epithelium. The autopsy showed beginning glomerulo-nephritis. Death was due to malignant disease of liver. (2.) The average of nineteen measurements in a case of rheumatism, for which the patient had been taking salicylic acid and salicylates, was 941.5 cub. cent. The urine contained a trace of albumen and hyaline casts, both of which entirely disappeared before the patient left the hospital.

Such cases are the ones in which mistakes in diagnosis are the most frequent. For instance, I have known of a diagnosis of chronic Bright's disease being made in a case of cerebral disease, in which the urine contained a trace of albumen and the sediment hyaline casts, with blood and renal epithelium; yet the amount of urine was about normal, and more than fifty grams of urea were being eliminated,—a condition of things which should lead one to give at least a doubtful diagnosis, so far as the kidneys are concerned, and wait for time to show whether a temporary or permanent affection existed. In this case the casts and albumen have entirely disappeared.

In typhoid, rheumatic, and other fevers we often see

in the urine a few hyaline casts and a trace of albumen, with a diminished amount of urine. In these cases parenchymatous disease of the kidneys can be eliminated by the character of the sediment and the proportion of albumen, but those renal diseases characterized by only a trace of albumen and the same composition of the sediment can only be eliminated with absolute certainty by waiting until the fever has subsided and examining again, although a normal or increased amount of solids, with the diminished amount of urine, points very decidedly to the absence of any serious renal disease.

In many cases of acute rheumatism, especially after the exhibition of salicylic acid and the salicylates (as in Case 2 above mentioned), I have found a trace of albumen in the urine and hyaline and finely granular casts, with blood and renal epithelium in the sediment. I have not yet a sufficient amount of material to be able to form an opinion as to whether the salicylic acid has anything to do with this condition or not. I have seen some of these cases in which the casts and albumen entirely disappeared, but in which the diagnosis of chronic Bright's disease had been made; an error which would not have occurred had due regard been paid to the amount of work which the kidneys were capable of doing, and to the average daily amount of the urine.

EUROPEAN AND AMERICAN ANATOMY ACTS COMPARED.

BY EDWARD MUSSEY HARTWELL, M. A.,
Fellow of the Johns Hopkins University.

THE Greek anatomists at Alexandria, 300 B. C.; Mondino de Luzzi in Italy, 1300 A. D.; Vesalius in France and Spain, in the sixteenth century; the Hunters in England, and Shippen and Warren in the United States, in the latter half of the eighteenth century; Knox in Scotland, and his contemporaries in England and America, in the first third of the present century, have all been obliged to contend against the hostile forces of popular prejudice and legislative indifference. The influences which to-day work to the detriment of anatomical studies in so many of our American States are strangely compounded of pagan superstition, Christian materialism, and a natural repugnance to the untutored mind and manners of the average medical student. European and American anatomy have both developed along the same lines; but the European type is more highly specialized. Nearly all the developmental stages through which European anatomical science has passed are to-day represented in the various States of the American Union.

It is noteworthy that in its earliest stages anatomy depended on the favor of princes. Ptolemy Soter founded the Alexandrian School 300 B. C. "Braving all prejudices, and considering that the interests of science ought always to outweigh those of the individual, Ptolemy authorized the dissection of human dead bodies, and himself set the example by beginning to dissect with the physicians gathered about him."¹ "In the year 1238, Kaiser Frederic II. ordered, at the suggestion of Marcianus, sub-chief physician of Sicily, that every five years a corpse should be publicly dissected [in Sicily], and that physicians and surgeons

should be admitted, according to their rank, to the dissection."² The favor of Ptolemy and Frederic II. has, perhaps, its modern parallel in the judicious blindness of the American chief of police as to what transpires in the potter's field.

It is not usual to find the prototype of our city fathers in the early fathers of the church; but there is certainly a strong generic resemblance between the doctrine of Tertullian that the bones and teeth remain unchanged "in order that they may fructify as seeds in the resurrection of the body," and the reason given recently by a commissioner, in one of our principal cities, for refusing the request of certain anatomists for bodies required to be buried at the public expense, namely, that dissection would prevent their resurrection.

It is customary to state or imply that the church anathematized dissection. There is every reason to believe, however, that the oft-quoted edict of Pope Boniface VIII., issued in 1299, according to Raynaldus, against the boiling, drying, or cutting up of the dead, was not aimed at the anatomists, but was intended to reform certain obnoxious burial customs. In 1482, Pope Sixtus IV. granted the rector, doctors, and students of the University of Tübingen a special dispensation to take the bodies of certain criminals executed under the civil law, in order that they might thereby become expert and learned in the art of medicine, provided they would bury the same dead bodies in the customary manner after they should be dissected and dismembered.³ Hyrtl holds that the edict of Boniface VIII. remained in force as an obstacle to anatomy till 1556, when the divines of Salamanca, in reply to the inquiry of Emperor Charles V., the patron of Vesalius, declared that human bodies might be dissected with "a blameless conscience and without suspicion of criminality."⁴

The following chronological statement may serve to indicate how essentially mediæval is the present attitude of certain American States regarding practical anatomy. For the sake of brevity, the authorities consulted are not cited:—

The Great Council of Venice in 1308 passed a decree ordering the medical college of that city to undertake a dissection once a year. In Prague, as early as the founding of the university, in 1348, the executioners were enjoined to deliver the dead bodies of malefactors to the medical school. In 1376, Duke Louis of Anjou granted the medical faculty of Montpellier, in France, the privilege of taking yearly the body of an executed criminal for dissection. In 1377, Charles the Bad, King of Navarre and Lord of Montpellier, confirmed the grant. In 1404, the first anatomical demonstrations were made before the medical faculty of Vienna. Duke Albert IV., having imported Galeazzo de Santa Sofia, an Italian anatomist, to introduce the art of dissection, July 1, 1505, the town council of Edinburgh granted the Surgeons' Company to "have anis in the year ane condampnit man efter he be deid to mak anatomie of." It was enacted, 32 Henry VIII., chapter 42, 1510, that the Mystery and Commonalty of Barbers and Surgeons of London might "take yearly forever . . . four persons condemned, adjudged and put to Death for Felony . . . to make

Incision of the same dead Bodies . . . for their further and better Knowledge, Instructions, Insight, Learning, and Experience in the said Science or Faculty of Surgery." It is possible that Governor John Winthrop, who was read in physic, may have authorized the first anatomy in the colony of Massachusetts Bay, as Mr. Giles Firmin, who made it before 1647, was a connection of Governor Winthrop. Prior to the Revolution the royal governors could order the dissection of a murderer's body. In 1778 the State of Virginia refused to sanction the dissection of executed murderers, and has apparently remained in a state of arrested development ever since, so far as any appreciation of the claims of anatomy are concerned. Massachusetts, in 1784, passed a law allowing the dissection of dead duellists, thereby unwittingly reproducing in spirit, though not in letter, a canon of the mediæval church, which denied Christian burial to men slain in tournaments. New York, in 1789, in order that science might not be injured by its law of that year regarding disinterment, made it lawful for the courts to add dissection to the death penalty in cases of murder, arson, and burglary. The First Congress of the United States, by the act of April 30, 1790, gave federal judges the discretion of adding dissection to the sentence of convicted murderers. A similar act was passed in New Jersey, in 1796. No trace of progress worth mentioning, in this class of legislation, since the enactment of the above-noted laws, is to be found in the most recent revisions of the statutes either of the United States or of New Jersey.

The dissection of executed criminals, as such, is still lawful within the special jurisdiction of the United States government and in the following States: Alabama, Arkansas, Colorado, Connecticut, Georgia, Illinois, Indiana, Kansas, Massachusetts, Missouri, Nebraska, and New Jersey. Nebraska, like the United States and New Jersey, makes no provision other than this for its anatomists. Unlike them, however, it has a penal statute regarding grave robbery. Alabama, Georgia, Missouri, and Tennessee allow the dissection not only of executed criminals, but also of "other persons with the consent of their friends." Maine should not be classed with these States since 1876, when capital punishment was abolished within its borders. Tennessee retains a useless permission to anatomists to dissect "the remains of slaves with the consent of their masters."

Kentucky, Mississippi, Oregon, Rhode Island, Texas, Virginia, and West Virginia are without laws of any kind regarding dissection, though they all forbid violation of sepulture. The most backward of the United States are those which have no statute touching either dissection or grave robbery. In this class we find Delaware, Florida, Louisiana, Maryland, Nevada, North Carolina, and South Carolina. The Territories of Arizona, Idaho, Montana, and New Mexico are similarly indifferent to the science of anatomy and the sanctity of burial-places. Certain of these States, like Maryland and Louisiana, contain medical schools. In order to punish body-snatching Maryland is to-day obliged to fall back on the common law of England, although the common law penalty was superseded nearly fifty years since by the passage of the Warburton anatomy act. All things considered, the attitude of the Italian cities of the fourteenth century and that of the empire of Japan of to-day must be characterized as more liberal and enlightened regarding the alpha-

bet of medicine than that of the United States and of very many of the individual States. France, in 1790, and England, in 1832, recognized the impolicy of employing dissection as a mark of infamy by repealing the laws allowing the dissection of murderers.

In the Privilegia granted by the Landgrave Wilhelm von Hessen to the University of Marburg, in 1653, it is provided that "in the medical faculty at the start there shall be two doctors in pay, who, in addition to the theory, shall conduct the practice of anatomy and of botany with the youth." The statutes of the medical faculty at Marburg for the same year, Title IV., read as follows:—

"(1.) It is clear that anatomy, next after psychology, forms the chief part of universal physiology. Since there is a twofold method of teaching it, one that is ordinarily practiced in anatomical theatres in the presence of many spectators, and the other which is employed by the holders of scholastic chairs, let neither of them be intermitted. Let both of them, as well publicly as privately, be practiced.

"(2.) Let also the art of dissection and of skillfully handling and applying the knife in individual parts be shown, in order that a difference may be noted between physical and medical or practical anatomy. The various skeletons, also, both male and female, of common and exotic animals shall be prepared, in order that not only the structure of the skeleton, but also the whole of osteology, may become known to students of medicine as well as of surgery.

"(3.) Let pregnant women be dissected as well as others. Let midwives as well as others be admitted.

"(4.) Let not those who are condemned to death be opened alive, but let living things of every kind, as insects, serpents, aquatic animals, birds, and quadrupeds, be dissected. Especially let those studying anatomy observe more precisely than butchers would domestic quadrupeds while they are being slaughtered.

"(5.) Moreover, let the bodies of atrocious criminals, whether they have been beheaded or hanged, be designated for dissection. Let them not be kept back by the magistracy when they are sought for this purpose, in order that those who have done as much evil as they could when alive may, after death, on the other hand, be of as much service and use as possible."

France in 1798, Massachusetts in 1831, and England in 1832 gave enlarged expression to the principle enunciated in Section 5 of the Marburg statutes by making it lawful to surrender, for anatomical purposes, the bodies of persons required to be buried at public expense. The following named States have imitated the lead of Massachusetts in legalizing such delivery: Arkansas, California, Connecticut, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, New Hampshire, New York, Ohio, Pennsylvania, and Wisconsin.

Notwithstanding the numerous privileges granted to anatomists by kings and popes and parliaments, recourse to "outside sources" of supply for subjects was often necessary. This is evident from various regulations concerning medical students. For instance, on February 1, 1630, the parliament of Paris passed a decree forbidding medical students from taking by force the bodies of executed criminals, and prohibiting prefects and executioners, also their servants, from delivering such bodies to students without an order signed by the dean of the faculty of medicine. When this decree was under discussion it was said that "for a long time the students of medicine and surgery had

indulged in deeds of violence and had even committed murder in order to get the bodies of criminals, and to that end had stirred up vagabonds, pages, and lackeys to raise an uproar, and favor in that way their removal." In 1632 students were again forbidden to remove by force the bodies of malefactors in a decree which provided as a penalty for such an offense a fine of one thousand livres of Paris. In 1722 the apprentices of the Surgeons' Company of Edinburgh were obliged to subscribe to the following additional obligation in their indentures: that "they would altogether avoid raising the dead." Dr. J. C. Warren and Dr. H. I. Bowditch, in works heretofore cited in these articles, have shown what was expected of medical students in New England seventy-five years ago.

(To be continued.)

DETECTION OF ARSENIC IN WALL PAPERS.

BY WILLIAM B. HILLS, M. D.

IN a recent number of the JOURNAL, the nitrate of silver test is spoken of as the "most simple and reliable test for arsenic in wall papers." This statement has lately been made in several medical journals, and doubtless originated in a paper read last summer before one of the British medical societies. The wide publicity which it has received seems to me a sufficient reason for stating, briefly, why it is one of the *least* reliable tests for the purpose mentioned. The cases in which the nitrate of silver test gives fairly reliable results are comparatively few, and are essentially those in which arsenite of copper (Scheele's green) or aceto-arsenite of copper (Schweinfürdt green) is used as a pigment, unmixed with other substances. These arsenical compounds are, however, seldom used thus, but are commonly employed mixed with other substances, by which means the green color is modified and various tints are obtained, in which, as a rule, the arsenical green cannot be detected by any physical appearance. Under these circumstances the above test will ordinarily fail to indicate the presence of arsenic, and particularly so if the arsenical green is mixed with organic pigments. Many of these latter, when treated with ammonia, furnish colored liquids, the color varying with the nature of the organic pigments. If nitrate of silver is added to such a liquid, any precipitate produced, whatever its true color may be, will ordinarily *appear* of the color of the liquid; for example, yellow arsenite of silver will generally *appear* red in a red liquid. Obviously, no conclusion can be drawn in such cases as to the presence or absence of arsenic. Moreover, various organic solutions give precipitates with ammonio-nitrate of silver, even in the absence of arsenic. If arsenious acid is present at the same time, the light yellow arsenite of silver produced is easily obscured by these organic compounds. On this account the test is often of no value.

Even if we obtain a yellow precipitate, we cannot say positively that it is due to arsenious acid, unless we are dealing with one of the characteristic greens, and at the same time get with ammonia the characteristic blue color due to copper. I have several times obtained from wall paper, by nitrate of silver, a yellow precipitate, when other tests proved the absence of arsenic. This precipitate is probably phosphate of

silver, which cannot be distinguished by physical appearances from arsenite of silver. (It is well to say here that the yellow precipitate due to arsenic is the *arsenite* of silver and not the *arsenate*, as the journals copying this test all have it.)

But arsenic may and in fact usually does occur in paper in other forms than those mentioned. The yellow sulphide of arsenic is sometimes used, and the arsenic in such cases cannot be detected by nitrate of silver.

One of the most common forms in which arsenic occurs in paper is as an impurity in the aniline colors so much used as pigments. Arsenic acid is very extensively employed in the manufacture of aniline colors, which are often sent into the market still retaining a considerable proportion of arsenic. The various shades of red are especially liable to contain arsenic from this cause, though many of the other aniline colors do contain it. With papers printed with these pigments ammonia usually produces the colored liquids above mentioned, which may disguise the true color of any precipitate produced by nitrate of silver. In the aniline colors arsenic is present chiefly as arsenic acid, which with nitrate of silver and ammonia gives a *red* precipitate, arseniate of silver. Here also the test is useless. If the pigment is a red one, soluble in ammonia, we cannot say whether we have obtained a red precipitate, or whether the precipitate *appears* red because it is suspended in a red liquid. Even if red itself, it may be due to organic matter and not to arsenic acid.

The arsenic may not be in the pigment at all, but in the mordant employed to fix the pigment. Arseniate of alumina is thus used. Ammonia will probably not remove this from the paper. Even if it did the test is useless for the reasons stated.

Arsenic occurs in paper in still other forms. Without mentioning these, the facts stated show that a person employing the nitrate-of-silver test alone will necessarily report most arsenical papers as free from arsenic, and will be in danger of reporting, as arsenical, papers entirely free from arsenic.

My method of proceeding is as follows: Take a sample three or four inches square (less will suffice with plain papers), cut into small pieces, moisten with concentrated sulphuric acid and heat carefully till the paper is thoroughly charred. Let the charred mass cool, add to it about one fluid ounce of water, grind the black mass fine that the water may come in contact with all parts of it, filter and wash. The arsenic will be found in the filtrate, which is examined by Marsh's test. All chemicals must be free from arsenic. A paper which, treated carefully in this manner, furnishes no arsenical mirror on porcelain does not contain any appreciable amount of arsenic.

RECENT PROGRESS IN GYNÆCOLOGY.

BY W. H. BAKER, M. D.

SIXTY-SEVEN CASES OF UTERINE DISPLACEMENT.

DR. GRAILY HEWITT reports these cases to the London Obstetrical Society.¹ The treatment which in a large majority of them proved successful consisted of rest in such positions of the body as would relieve the uterus

¹ British Medical Journal, June 26, 1880.

of abdominal pressure; attention to diet with an abundance of food, which oftentimes had to be given in small amounts each hour; the use of the cradle pessary for forward and the Hodge for backward displacements; and, as subsidiary measures, the sponge bath, friction of the skin, and great care to prevent constipation.

The cases offer strong evidence of the connection between the health of the body generally and that of the generative organs, especially the uterus; and they show that if the strength be not adequately sustained during the growing age, the uterus is liable to suffer and to become weak and incapable of resisting the physical strain and tension of an ordinarily active life. Local uterine treatment cannot therefore be expected to be permanently successful unless measures be taken to remedy the extreme general weakness. The physical change most evident in the uterine tissues, in the cases of prolonged insufficiency of food, was softening and loss of tonicity.

Another general conclusion arrived at by the author from his observations was the remarkable frequency with which the patients were afflicted with physical powerlessness, an incapability for locomotion varying in degree. Physical exertion produced a temporary exaggeration of the existing internal malady, caused pain, and was then given up. Hence, in many cases, a helpless invalidism. This physical inability was not imaginary or fanciful, though often erroneously so considered.

Dr. Hewitt urged the removal of pessaries at moderately short intervals, for the sake of observing the position of the uterus, as well as for cleanliness.

PROLAPSE OF THE OVARIES.¹

The subject of this very valuable article is one whose importance has not been generally felt, judging from the extreme brevity with which authors have treated it. The anatomy of the ovaries and their relations to the adjacent viscera are first considered by Dr. Mundé, and from the table introduced from Farre it appears that the average longitudinal diameter of the ovary is 1" 4", the transverse diameter 9", and the perpendicular diameter 4.5". From another table, introduced from Hennig, the fact is shown that the distance of the ovaries from the uterus is nearly twice as great in puerperæ as in married women, and more than twice as great as in virgins. This is important to remember, as bearing upon the establishment of the fact that frequent child-bearing, with its correspondingly frequent stretching of the attachments of the ovaries to the uterus, predisposes to prolapse of these bodies. The ovary is sustained in its movable position, first, by the posterior layer of the broad ligament; second, by the ovarian ligament; third, by the infundibulo-ovarian ligament; and a very slight support may be afforded by the thickening of the upper border of the broad ligament by the Fallopian tube. The projection of the ovary posteriorly, the mobility of the broad ligaments and their inclination downwards and backwards, show the tendency of the ovary to glide into Douglas's pouch, — a tendency materially increased by the lengthening of the ovarian ligament in consequence of repeated pregnancies and the dragging of the enlarged ovaries.

In regard to the palpation of the normal ovaries, the author says that in women with relaxed, compressible abdominal walls and a soft, non-rigid vaginal vault it

is frequently possible to palpate the normal, non-prolapsed ovaries, one finger (preferably the left index for the left, the right for the right ovary) pushing up the corresponding vaginal cul-de-sac, and the other hand pressing down the abdominal wall immediately over it. By then rolling the pelvic organs gently over the internal finger with the external hand, the ovary can frequently (and the tube occasionally) be felt, and its size and shape clearly mapped out. If perfectly healthy, moderate palpation gives but slight pain, and that of a dull character. In sixteen hundred unselected gynecological cases, the author found it possible to examine the ovaries in one hundred and forty-five. From the statistics given, it is shown that the prolapse of the ovaries laterally or backwards constitutes by far the greater majority of all cases of dislocation.

The various conditions given as favoring or producing dislocation of the ovary are: (1.) Enlargement of the ovary. (2.) Displacement of the uterus. (3.) Relaxation of the supports of the uterus and ovaries. (4.) Inflammatory adhesions. (5.) Sudden jarring or concussion of the whole body. (6.) Pressure from above, as by tumors, fecal accumulation, etc.

The symptoms produced by prolapse of one or both ovaries (if any inconvenience be experienced) are: a dragging sensation in each groin and down the thighs, some bearing down and weight in the pelvis, sacralgia, pain in either hip, slight radiating neuralgic pains in the groins and thighs, a numb, sickening pain during coition, and difficult defecation, owing, of course, to direct pressure on the ovary. The general symptoms are an excess of irritability, of "nervousness," similar to that usually occurring during the menstrual period.

The displacement of a congested and enlarged ovary excites symptoms of vastly greater intensity. The patient complains of a burning, throbbing, heavy sensation in the pelvis and sacrum; of a feeling of obstruction, alternating with tenesmus, in the rectum; of frequent darting, shooting pains in one or both groins, generally the left, and through the pelvis and down the thighs; of nausea and irritability of the stomach; of painful coition and defecation, generally in a high degree. Usually, every movement of the cervix uteri by the exploring finger causes great pain through traction or pressure on the ovary. A vaginal examination ordinarily produces an exacerbation of pain for one or more days.

In the treatment of these cases, the indications are obvious, namely, to restore the displaced organs to their normal position. If the ovaries are movable, not bound down by adhesions, this is easily done. The knee-breast position is the best for such replacement. The perineum should then be lifted with Sims's speculum, when the vagina becomes distended to its utmost capacity. If the ovaries still remain within reach, both fingers should be pressed into the posterior cul-de-sac of the vagina, and each ovary gently lifted up and pushed forward with a quick motion, so as to cause it to fall forward and downward into the abdominal cavity. Should the fingers not suffice for this manœuvre, the sponge-holder or vaginal depressor may be used, or similar efforts may be made through the rectum.

The adaptation of means to retain the prolapsed ovaries when replaced is as difficult as their reposition is easy. Having been replaced, they may be retained by the introduction of a pessary so constructed as to fill the retro-cervical pouch and leave no space between the uterus and the sacrum. Such a pessary is that devised

¹ Paul L. Mundé, M. D., Transactions American Gynecological Society, volume iv.

by Thomas, and known as the bulb pessary. When the prolapsed ovaries are enlarged, inflamed, and hyperæsthetic, their reposition may succeed, but the immediate introduction of a pessary is usually impracticable. If they are very much inflamed, the better plan is to confine the patient to her bed for a few days, and by antiphlogistic measures (hot vaginal baths, tincture of iodine to the vaginal vault, glycerine tampons, perhaps leeches to the cervix) endeavor to allay the inflammation before attempting the reduction and application of a permanent support. If the parts should still be too tender, the posterior vaginal cul-de-sac first, and then the whole vagina, should be gently but firmly packed with disks of cotton, sheep's wool, or marine lint, soaked in carbolized glycerine and squeezed dry, and introduced one by one, until the uterus and vaginal roof have been furnished a soft and firm support. This tampon should be renewed each twenty-four or forty-eight hours.

If the prolapsed ovaries, besides being inflamed, are attached to the bottom or sides of Douglas's pouch by fresh or old adhesions, our therapeutical measures are restricted to the removal of the inflammatory signs and the relief of pain by the remedies already indicated, namely, narcotic rectal suppositories, preferably hyoscyamus, cannabis indica, and iodoform, if sufficiently powerful, instead of opium. If these do not avail, and the regularly recurring menstrual oöphoro-neuroses endanger the intellect, the removal of the ovaries may be the only hope of cure; and this may be a scant one, on account of the greatly increased danger to life from the operation under these circumstances.

MEASUREMENTS OF THE UTERINE CAVITY IN CHILD-BED.¹

Dr. A. D. Sinclair contributes a paper with statistical tables based upon one hundred and eight cases, observed either by himself or Dr. W. L. Richardson. The importance of these experiments is readily seen when we consider that we were formerly taught that six or eight weeks were required to accomplish the involution of the uterus; whereas it is here shown that the process, in the large majority of cases, is completed within eighteen days, as measured by the sound passed carefully into the uterine cavity; and this, too, when, in a large proportion of the cases, the patients were suffering from some complication, as fissures of the cervix or perinæum, etc., etc., which are likely to have a deleterious effect upon involution. The author expresses the hope that these experiments may be pursued by others, and that at some future time more extensive results may be obtained.

— In the last session of Congress of the United States at Washington, May 24, 1880, the committee on naval affairs reported a bill in support of a proposed international commission to agree upon standard tests for color-blindness and visual power in navies and merchant marines, and standard requirements of these faculties. Resolves in recommendation of this commission have been passed by the American Ophthalmological Society at their Newport meeting, the ophthalmological section of the British Medical Association at Cambridge, and the International Congress of Ophthalmology at Milan. The next United States Congress will act on this bill to initiate the commission.

Hospital Practice and Clinical Memoranda.

NOTES OF CHANGES SEEN IN THE EYES OF TEN CASES OF GENERAL PARALYSIS OF THE INSANE.

BY CHARLES H. WILLIAMS, M. D.

THROUGH the kindness of Dr. H. R. Stedman, I lately made an ophthalmoscopic examination of ten cases of general paralysis at the Danvers Hospital, and as the number of recorded cases is not large the following notes are given:—

	Duration of disease.	Size of pupils.	Reaction to light.	Ophthalmoscopic changes in fundus.
No. 1. E. B. H.	Under 1 yr.	Small.	Poor.	No change.
No. 2. C. D.		Small.	Poor.	No change.
No. 3. J. W. D. S.		Left smaller than right.	Poor.	Both eyes, disc reddish gray; arteries slightly contracted; scleral ring well marked, especially in right.
No. 4. W. D.		Small.	Poor.	Both eyes, disc slightly whiter; arteries smaller than normal.
No. 5. G. F. S.	3½ yrs.	Small.	Poor.	Both eyes, disc slightly whiter than normal; blood-vessels unchanged.
No. 6. J. B. S.	4½ yrs.	Small.	Poor.	Both eyes, disc whiter than normal; arteries smaller; the surface of discs has a slightly hollowed, excavated look.
No. 7. M.		Normal.	Good.	Right eye, a slight band of white fibres crosses over the vessels just before they pass out from the disc.
No. 8. B. F. L.	1 yr.	Small.	Sluggish.	Both eyes, slight hyperæmia of disc; veins somewhat enlarged.
No. 9. E. M.	1 yr.	Normal.	Poor.	Both eyes, disc striated and tendoned; on temporal side not to be distinguished from general tint of fundus; veins slightly enlarged. With ophthalmoscope a hypermetropia of 6 dioptres was found in each eye. Lens of right eye had a small opacity in anterior part in head of pupil.
No. 10. D.		Small.	Poor.	Crescentic posterior staphyloma on outer border of disc; myopia; otherwise normal.

Different observers have reported various ophthalmoscopic changes in this disease; John having found about fourteen per cent. of atrophy of the optic nerves, and Albutt speaking of a preliminary stage of congestion which some others have failed to see.

In the above cases it will be noticed that the commonest symptoms were small pupils, with slow and poor reaction to light, when the eye was quickly illuminated by the mirror.

In four cases no change was noticed in the fundus which could be referred to the nervous disease.

In four cases, including Nos. 5 and 6 where the disease was of three and one half and four and one half

years' standing, slight signs of atrophy were found at the disc, which were most marked in the case of long-standing.

In two cases, each of about a year's duration, evident signs of congestion were seen about the disc; in one case a slight hyperæmia, in the other an appearance of slight neuritis; but in this case there was also found an uncorrected hypermetropia of some six dioptries, which may, to a certain extent, account for the greater congestion.

Attempts were made to ascertain the acuteness of vision and other data; but the answers were found, in most cases, to be unreliable.

IN-GROWING EYE-LASHES.

BY DAVID COGGIN, M. D., SALEM.

THERE are few general practitioners who have not had patients, chiefly from the laboring class, suffering from trichiasis, commonly of the upper eyelid, and sometimes in such a degree as to almost incapacitate them from following their usual avocations. Heretofore the many operations that have been performed for its relief have by no means been wholly satisfactory, while the execution of some of them has been the reverse of facile.

In the *Annales d'Oculistique*, tome lxxxi., page 146, Dr. Warlomont, the well-known ophthalmic surgeon of Brussels, speaks highly of an operation, devised by Anagnostakis, and modified by Lebrun, which is thus done: After arresting the circulation in the affected lid, by means of Snellin's or any other suitable clamp forceps, an incision is made through the skin only, along the entire length of the lid, and about two mm. distant from the row of lashes; then the upper flap (embracing the skin alone) is dissected as far as the superior border of the tarsal cartilage.

This done, four or five fine catgut sutures are inserted by means of a hollow needle (but an ordinary one in a good holder answers very well). The needle is thrust through the skin between the lashes and the line of the incision (the dissected flap being held up out of the way by an aid) and is then made to pass under the connective tissue and the orbicularis muscle and along the cartilage till it emerges at, or a little above, its superior border. These sutures, which are perpendicular to the edge of the lid, and equidistant from each other, are tied so as to strangle the tissues included in them. The dissected flap of skin is now drawn down in place, and the sutures are thus concealed. The sutures gradually cut through the parts beneath, with but little suppuration, and become absorbed, leaving cicatricial tissue behind, which helps to maintain the upturned margin of the lid in its new position. The distinguished advocate of this operation claims for it many advantages over the older ones, among which are these:—

It is subcutaneous and leaves no visible scars, which in some cases is obviously very important.

Its effect is to correct the position of the tarsal cartilage, and at the same time to carry the ciliary border away from the globe.

In severe cases it readily allows the removal of a wedge-shaped strip of the cartilage, — Streetfield's operation (my results were the best when I did not thus groove the cartilage).

The fullness and mobility of the skin of the lid are not affected, nor is the integrity of the margin interfered with.

Dr. Green, of St. Louis, the American editor of *Carter on the Eye*, performs an operation similar to the above with the exception that he includes the skin in the sutures, while to facilitate the tilting out of the ciliary margin of the lid he makes "a bold longitudinal incision through the conjunctiva and tarsus, from one end of the tarsus to the other, and parallel to and about a line or a line and a quarter distant from the free border of the lid." The groove made by it is allowed to fill with granulations, which tend to remove still further the misplaced lashes from the eye. This incision apparently proved an important addition in some of the cases in which I tried it, and I opine that its performance is likely to be ordinarily attended with better success when doing the above described operation than when it is omitted.

In the original Anagnostakis operation the needle is carried immediately up beneath the skin, or rather on the surface of the exposed muscle, till it enters the fibrous tissue covering the cartilage, while by the Lebrun method it passes beneath the connective tissue and muscle. It was by following the first procedure that I attained the best results (combined with the conjunctival incision), though as yet I have not operated enough times to allow me to speak *ex cathedra*. It should have been stated earlier that, on drawing down the dissected flap of skin over the seat of the sutures, it is not necessary to unite the cutaneous edges of the wound with sutures, as immediate union occurs and in a short time there is scarcely a trace left of the incision. Only the lightest, if any, dressings are required. Within three days after being operated upon, laboring men have resumed their work without inconvenience.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. KOTCH, M. D., SECRETARY.

DECEMBER 27, 1880. DR. JAMES C. WHITE, permanent chairman, presided.

DR. E. S. WOOD read a paper on *The Average Daily Amount of Urine: Its Importance in Diagnosis*, which may be found on page 25 of this number of the JOURNAL.

DR. T. B. CURTIS thought that Dr. Wood's paper was exceedingly interesting and instructive, as an opportune protest against an error still too prevalent in the profession, which consisted in supposing that the examination of single specimens of urine could suffice to establish or controvert the diagnosis of renal disease. Samples of water were often sent to the urinary analyst with the expectation that a statement of the condition of the kidneys would be returned in exchange. It is now, however, universally recognized by all the authorities that albuminuria may exist as a temporary functional disturbance, in the absence of any organic renal disease, if not, indeed, as lately maintained by Runeberg and others, in full bodily health. Such is also the case as regards the occurrence of certain forms of urinary casts. On the other hand, the most com-

mon and fatal form of chronic Bright's disease, namely, interstitial nephritis or renal cirrhosis, may be unattended by albuminuria, as well as by casts, dropsy, or renal pain, until an advanced or complicated stage of the disease. In certain cases, even, as shown by Bartels, Mahomed, and others, a fatal termination in cerebral uræmia may be reached without albuminuria having ever been detected, in spite of repeated careful examinations of the urine. Therefore "albuminuria" and "Bright's disease" have now ceased to be synonymous and exchangeable terms, though still erroneously so considered by many physicians and surgeons, and so laid down in the last edition (1869) of the nomenclature of diseases of the Royal College of Physicians of London.

The diagnosis of renal disease, in surgical as well as in medical cases, like that of typhoid fever, should be based mainly and primarily upon the rational signs and circumstantial evidence, rather than upon the presence or absence of albuminuria, casts, renal pain, and dropsy, formerly considered pathognomonic symptoms. In one kind of renal disease, namely, chronic parenchymatous nephritis, the urine is, perhaps, sufficiently characteristic, by its specific gravity, sediment, and abundant albumen, to allow of a correct diagnosis based solely upon the results of urinary analysis; but in the other forms of chronic disease of the kidneys, such as primary renal cirrhosis and secondary interstitial nephritis (sometimes called "surgical kidney"), the urine may at any period, or at all periods, be found normal or nearly so. The most valuable signs to be derived from the renal secretion in these forms of disease consist not so much in the qualitative changes, formerly alone considered significant, as in the variations of *quantity*, consisting chiefly of polyuria, upon the importance of which the reader has laid due stress.

In conclusion, Dr. Curtis would urge that we, as physicians, should bear in mind and imitate the wise caution shown by Falstaff's doctor. In the play of Henry IV. (Part II. Act I. Scene 2) the knight enters, followed by his page bearing his sword and buckler. "Sirrah, you giant," says Falstaff, "what says the doctor to my water?" To which the page makes answer, "He said, sir, the water itself was a good healthy water, but, for the party that owed it, he might have more diseases than he knew for."

In answer to a question by Dr. S. Cabot, Dr. Wood said that the daily amount of urine passed in health is about fifty ounces.

Dr. ELLIS called attention to the cases of hysterical anuria, where the secretion may cease for days without the appearance of symptoms so frequently associated with suppression.

Dr. T. B. CURTIS remarked that hysterical anuria or suppression of urine had been most carefully studied by Charcot among his patients at the Salpêtrière Hospital, and was fully described in his clinical lectures on diseases of the nervous system. In Charcot's hysterical patients the disturbance lasted several days, the longest duration recorded by him being ten or eleven days; in some vicarious vomiting existed. These cases remind one of the form of anuria described by Roberts under the name of "obstructive suppression of urine," due to blocking of the ureters by calculi. A "non-obstructive" form of suppression exists which occurs as a result of surgical procedures in the urethra or bladder, and accompanies severe "urethral fever." In these cases, which are apt to be rapidly fatal, recov-

ery is not uncommon after a duration of about twenty-four hours, but Sir Henry Thompson has seen but one recovery after forty-eight hours of such suppression. In the obstructive form, on the other hand, complete anuria may exist for many days, as many as fourteen or even twenty days,¹ with ultimate recovery, on the blocked ureter again becoming pervious to urine. For upwards of a week no urine may be passed, the bladder remaining empty, the patient eating and drinking as usual, and complaining of little or no distress or discomfort, except, perhaps, sleeplessness. Later, ominous symptoms, the first of which consists in muscular twitchings, are apt to supervene. Dr. Curtis had seen two such cases of obstructive suppression, due to blocking of the ureters, each lasting a week, and ending in recovery, with voiding of the calculi.

Dr. WEBBER said that the measurement of the urine is valuable not only for diagnosis, but also is of as much importance to aid in forming a correct prognosis, and to guide in the treatment. This is especially true in parenchymatous nephritis, whether acute or chronic. If the amount passed in the acute disease varies according to the course described by Dr. Wood as favorable, the prognosis is of course favorable; if, however, the amount is persistently small, it is less favorable. In chronic diseases, if the amount passed is continuously much below normal there is more reason for apprehension, or if, having been considerable, the amount diminishes, the prognosis is less favorable than when nearly the normal amount is passed. Also, in treatment, a knowledge of the amount of urine passed daily is a valuable guide, a diminution in the amount indicating that other or more decided measures are called for. While administering digitalis a sudden diminution in amount of urine is of great importance as pointing the probability that that drug is acting unfavorably.

The effect of hot air or hot-water bath upon the secretion of urine in acute or chronic nephritis is of interest. The benefit is most marked in freshly acute cases, or where an acute attack supervenes upon an old chronic disease. The hot-air bath may be used with comparatively vigorous patients at a temperature of 110° F. to 130° F. for fifteen to thirty minutes. The object being to act on the skin in producing perspiration, it is not necessary to increase the heat after the skin acts freely, though the temperature may be but slightly raised. Feeble patients, of course, bear the bath less well than the vigorous, and it should be used in such cases with caution, especially if there is cardiac complaint. Hot-water bath, 100° F. to 105° F., for fifteen to thirty minutes will sometimes act better than the hot-air bath, and has the advantage of its cleansing effect. The day after the urine will frequently show a marked increase in amount, and severe dropsical effusions may speedily disappear under such influence. Unfortunately, some patients who most need this relief cannot be made to sweat by these means.

Dr. ELLIS inquired whether the amount of water taken during and after the hot-air bath had been noted, as he considered this an important factor in explaining the increase of urine.

Dr. WEBBER remarked that a theory may be given for the action of the hot bath: The equilibrium between the tension of the vessels and the secreting power of the kidneys is changed by disease, and thus

¹ See a case reported by James Russell, Medical Times and Gazette, November 27, 1880, page 616.

a variation of tension which would not be noticed in health may cause a diminution of secretion; the action of the skin will then relieve the kidneys in a chronic case, just as the same relief is obtained in acute congestion, and the equilibrium which is most favorable for the action of the diseased kidneys is restored.

DR. J. J. PUTNAM spoke of the cold pack causing greater activity of the circulation and furnishing more water without any increase of the amount taken, thus perhaps answering the question of Dr. Ellis.

DR. ELLIS suggested that the elimination of injurious elements through the skin might relieve the nervous centres, and by this means the action of the heart might be increased, with the usual result of increasing the amount of urine.

DR. T. B. CURTIS was inclined to doubt if any true diuretic agent existed which acted as a direct stimulant of the renal secretion, without being dependent for its diuretic effects upon cardiac stimulation or upon the collateral ingestion of large amounts of water. Saline substances introduced into the blood cause thirst and drinking of water, whereby diuresis is brought about. Here the water is the diuretic. Digitalis is commonly supposed to be a true diuretic; but, according to the elaborate experimental and clinical investigations of Professor Hirtz (of Strasburg), this drug does not act at all as a diuretic when administered to healthy subjects; in heart disease, on the other hand, when cardiac failure supervenes, with lowered arterial tension, venous stagnation, and *dropsy*, then digitalis in suitable doses produces diuresis by enabling the enfeebled heart to pump out the dropsical effusions. The diuretic effect is the measure of the utility of the medication; when the quantity of urine begins to diminish digitalis has ceased to be useful.

DR. T. B. CURTIS inquired of Dr. Webber whether he had had any experience of the use of digitalis as a cardiac stimulant in the late stages of chronic interstitial nephritis, when failure of the heart had set in and uramic symptoms were observed or apprehended.

DR. WEBBER replied that he could not remember such a case with sufficient detail to mention the particulars, but that he was in the habit of using digitalis in nephritis under all conditions where it promised benefit, and that he considered it a very valuable agent.

MYELITIS.

DR. WEBBER reported the following case:—

About a month ago a patient entered the City Hospital whose case is of some interest. He had visited a friend the day previous to his admission, and sat outdoors in the cold for an hour or two; felt chilly. On admission he had not passed water for nearly twenty-four hours; forty-five ounces were drawn. The next day there was numbness, very slight in degree, in both legs, increase of tendon-reflex, and slight motor weakness in the legs. The numbness continued only a few days; he was soon able to pass his urine. The motor symptoms remained nearly stationary. He seemed but slightly ill, and in a fair way to recover, but he subsequently became weaker, motor power being most affected in the right leg. Sensation still remains unaffected. There has been lately retention of urine and cystitis, though he is improving again. The points of interest are the retention of urine occurring so soon after exposure, with so slight symptoms of spinal disturbance. Also the final development of the more serious symptoms after partial recovery from the slightest

is of interest, and the fact that motion is so much more affected than sensation.

BIMECONATE OF MORPHIA.

DR. T. B. CURTIS wished to call the attention of the society to a preparation of morphia, namely, the *bimeconate*, which he believed to possess advantages rendering it superior, for certain exceptional cases, to all other opiates. Morphia, in its natural condition in the poppy, is combined with meconic acid. The bimeconate, Dr. Curtis believed, was first introduced into therapeutics in 1839 by Squire, the author of the *Companion to the British Pharmacopœia*, in the form of a "solution of bimeconate of morphia," said to be of the same strength as laudanum, and to possess in an eminent degree the sedative powers of morphia, but having this superiority, that it disturbed the head, stomach, and bowels less than any other preparation of opium. For hypodermic use this solution, according to Squire, could be evaporated to one twentieth of its bulk, so that three minims were equal in power to a half grain of acetate of morphia. The bimeconate of morphia can now be obtained of druggists in the crystalline form, and can be administered in all the usual ways, like the other salts of morphia. In prescribing this salt, however, it should be borne in mind that it contains only half as much morphia as an equal weight of the sulphate. To obtain similar effects to those of the sulphate, therefore, a double dose must be given.¹

Dr. Curtis had recently met with three patients who were inconvenienced in various ways by opiates to such a degree that, although suffering much pain and distress, they were debarred from using these means of relief. One was an elderly lady who had for some weeks been afflicted with protracted hepatic colic and jaundice, due to gall-stones, and followed by severe hepatic pain and nausea. Opium and morphia caused intolerable nausea and vomiting; but the bimeconate, the use of which had already been suggested by her previous medical attendant (Dr. Daniel Stimson, of New York), was taken in fair doses with little or no inconvenience, and was productive of much relief and benefit. Another case was that of an old gentleman who greatly needed the assistance of anodynes, but preferred to abstain from opiates on account of the intolerable itching, combined with wakefulness, which invariably followed their administration. This patient, however, used the bimeconate in full doses successfully, without the production of pruritus. The wakefulness continued to follow the use of morphia, even in the form of the bimeconate, but a ten-grain dose of chloral added sleep to the relief from pain brought about by the anodyne. The third case was that of an elderly patient, of a neurotic temperament, suffering from a very protracted and severe epididymitis. Past experience had so convinced him of the ill effects produced in him by opiates that, when first seen by Dr. Curtis, the patient, although suffering severely every night, was using suppositories containing only one sixth of a grain of opium. The bimeconate was tried, and was taken nightly for many weeks in doses ranging from a quarter to three quarters of a grain without any ill effects.

Dr. Curtis did not regard his own experience as

¹ Sulphate of morphia, $2(C_7H_7NO_2)SO_4H_2 + 5H_2O$, contains 75.2 per cent. of morphia; the bimeconate, $C_7H_7NO_2 \cdot 2(C_7H_7O_7)$, contains only 41.6 per cent. of the alkaloid, or even a less percentage if combined water is present, as is usually apt to be the case.

sufficiently extensive to demonstrate conclusively the superiority of the bimeconate of morphia for the use of patients who were intolerant of opiates; but he thought that the results which he had obtained were sufficiently striking to warrant him in calling attention to this little-known remedy, in order that its efficacy might be tested and verified by other observers.

DEODORIZED TINCTURE OF OPIUM.

DR. T. B. CURTIS said that errors were frequently committed in the administration of the *tinctura opii deodorata*, a favorite opiate with many practitioners. The dose of this preparation is said to be the same as that of laudanum, of which thirteen minims or twenty-five drops equal one grain of opium. The deodorized tincture, however, is not really a tincture, but a watery solution of the extract of opium, and its drops are equal to minims. Therefore, if it is used in drops, like laudanum, a double dose will unintentionally be given. The dose in drops should not exceed the number of minims considered necessary.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

ANEMIA IN INFANCY AND EARLY CHILDHOOD.

At a stated meeting of the New York County Medical Society Professor A. Jacobi read an elaborate paper on the above subject. He commenced by saying that pathological processes were but the expression of physiological functions performed under abnormal conditions. The latter were anatomical in their nature, and he regretted to say that the anatomical predisposition of the different tissues to definite pathological states was a subject that was greatly neglected by the profession. As a general rule, every treatise on a special disease ought to commence with a statement of the anatomical predispositions of the part or parts affected by it. Thus, in the paper which he had read some time previously before the society, on the subject of infant diarrhoea, he had endeavored to point out that in early life there was a normal tendency to loose passages, partly on account of the anatomical characteristics of the intestinal tract, and partly on account of the nature of the food ingested. On the other hand, there was an obstinate form of constipation occurring in infants and young children, due to certain anatomical characteristics peculiar to that period of life, to which he had called the attention of the profession ten years ago, but which had not seemed to attract the notice which he believed it deserved. It had been found that until the third or fourth month of foetal life there was no colon ascendens whatever, and at birth this portion of the large intestine was still very short. Notwithstanding this, however, the colon descendens, and particularly the sigmoid flexure, was of excessive length in infants, and in the cases of constipation referred to it was the repeated bending of the elongated gut which interfered with the passage of the faeces.

Passing to the subject of rachitis, Dr. Jacobi alluded to the relatively large size of the liver and the arteries, the comparatively small lungs, and other anatomical peculiarities of the affection; and in this connection spoke of the influence of the abnormal abundance of cholesterine, from the increased size and activity of the liver, upon the osteous development. He then spoke of the characteristics of the lymphatic system on which

the development of the affection which we call scrofula depended, and stated that in his recent work on diphtheria he had pointed out that it was on account of the peculiar condition of this system, incident to early life, that the disease was especially dangerous in infancy.

He next considered the peculiarities of the blood at this period. In the newly born it had been found by Dennis in 1830 that the blood in the umbilical artery contained 22.2 per cent. of hæmoglobine, while in the vessels of the mother it contained only ten per cent. The high percentage of hæmoglobine met with at birth, according to Dennis, diminished until the age of six months, when there was a slow increase in its proportion up to the age of thirty years. The blood of the fœtus and of the newly-born child contained but little fibrin; but vigorous respiration soon made great changes in this respect. The infant and the young child had, and required, more blood in proportion to the entire weight than the adult; but the blood contained more salts and more leucocytes, with less fibrin and less albumen. With the increase of the size of the body the peripheral blood-vessels grew. The heart was relatively smallest, in proportion to the great size of the large arteries, during the first year of life, and particularly in its second half. The largeness of the pulmonary vessels made more active work for the lungs; but it also gave rise to a greater tendency to disease in the young.

In children, unlike adults, there was not only reproduction, but a constant growth, and hence all the organs were continually in occupation. There was an incessant busy metamorphosis of matter going on, and all this activity was at the expense of the system; the blood containing less solid constituents than that of the adult. In the healthy child there was the most accurate balance, so to speak, between its physiological capital and labor, and the slightest mishap was sufficient to derange this. The vulnerability thus being very great, cases of anæmia were met with every day in practice, and these were either uncomplicated or complicated, and perhaps incurable. Anæmia might be idiopathic or sympathetic. When the matter was sifted, it was evident that every such condition was in reality secondary, and could not therefore be strictly called idiopathic; but the same objection held good in regard to the use of the term in connection with all other affections. When the local trouble was not complicated with an affection that was recognizable and removable, it was sufficiently correct, therefore, to call it idiopathic.

The large majority of anæmias were of a secondary character, since every disease occurring in infancy was apt to give rise to anæmia, and very few affections could run their course without producing it. It was found also that one attack of disease in an organ usually predisposed the parts to subsequent ones.

Dr. Jacobi then alluded to various forms of hæmorrhages liable to occur in early life; after which he said that, as a rule, acute anæmia was more easily overcome than that of a more chronic character. It had been found that young animals were able to survive starvation for a much shorter period of time than older ones; and in the Prussian army it had been proved that the recruits which had been born in the years of famine were very much less robust than those born in other years. Of like character were premature children, and those born of delicate parents, who were liable to cyanosis, various forms of neoplasms, etc. Amongst the causes of anæmia in young children were acquired endocarditis, protracted diarrhoea or constipation, malaria,

leucoerythæmia, pernicious anæmia (of which only two cases at this period of life had been described), sleepless from any cause, rachitis, syphilis, fatty liver (which was more frequent than commonly supposed), enlarged lymphatic glands, the so-called scrofula, diseases of the lungs, and diseases of the bones, which were apt to finally result in amyloid degeneration of various organs.

In anæmia both the skin and mucous membrane were pale, or yellow, and flabby. The fat and muscular tissue usually failed first, but there were cases in which the fat remained, and was even deposited in increased quantities, on account of the incomplete combustion taking place in the system. This was apt especially to be the case in rachitis, and an illustration of the point was seen in the appearance of accephalic and other monsters, in which there was frequently a large amount of adipose tissue in consequence of the exclusively venous blood with which they were supplied. In anæmic conditions emaciation of the brain did not correspond with that of the rest of the body, — this organ being nourished at the expense of other parts of the system, — and hence any baby with depression of the fontanelles (which indicated emaciation of the brain) was to be considered in danger from inanition.

When murmurs were heard in the heart and large arteries in early life it was usually safer to attribute them to organic disease rather than to merely functional derangement; the trouble in all probability being due to acquired endocarditis.

This affection was much more common than was ordinarily supposed. It was usually the result of rheumatism, which in children was so much less marked than in adults that it sometimes escaped notice altogether, and was frequently mistaken for "growing pains." Yet, slight as the rheumatic trouble, it was much more apt to be complicated with endocarditis and to result in organic disease of the heart than when it occurred in adults.

Sometimes when children were noticed to cry and to sleep badly at night, this was due to simple anæmia, and a good night's rest might be secured by the proper administration of food or stimulus at bedtime. In infants and young children the condition of the pulse was one of the most unreliable of symptoms. During sleep it was better to feel it at the anterior fontanelle than in the radial artery; but if the child were awake it would be found that a little muscular exertion affected it perceptibly. Very few anæmic children had a good appetite, except, perhaps, at the beginning; and, as a rule, both appetite and digestion were markedly impaired in anæmia. Catarrhal trouble in the respiratory organs was also very frequent in this condition. In consequence of the thinness of the blood and the state of the vascular system, serous transudation was also apt to occur. In the same way anæmic women usually suffered from an unusually large menstrual flow. Again, acute diseases in anæmic children were, as a rule, much more serious than the same affections in robust children. As had before been stated, the predisposition to anæmia was very great in the young; and the causes producing it being so numerous great care was necessary to prevent its occurrence. The danger of anæmia was always greatest, as we would naturally expect, at the period of most active growth.

The nursing, therefore, was the most exposed to its risk, and the two great factors in its production at this

age were insufficient and improper food. Crying babies, it should not be forgotten, were often starving babies; and in such children any drain upon the system that occurred was almost sure to terminate life. Many an alleged case of constipation, when fully investigated, was found to be simply one of insufficient food. Improper food, however, was a much more frequent cause of anæmia than too little nourishment. Thus, nursing during pregnancy or menstruation was manifestly productive of the condition, and the same was true of diseased states of the mother from syphilis, anæmia, etc. Dr. Jacobi then gave a sketch of his well-known views on infant feeding when weaning became necessary, and stated that these had been expressed in full in the first volume of *Buck's Hygiene*. He also spoke of the general habits of life required in children in addition to proper feeding, and incidentally remarked that too many books and too few skates were bought for Christmas.

Amongst remedial agents, iron had long been considered as that which held the first place in anæmia and chlorosis. It had been believed to be of service mainly because it was supposed to have the property of increasing the red blood corpuscles; but this was still a doubtful point, and even if it did this to a certain extent it seemed to act beneficially in other ways also. There was plenty of iron in almost every article of food, and cases of chlorosis were continually occurring which could not, therefore, be due to merely a lack of iron. When iron was assimilated it was first dissolved in the form of an albuminoid, and it had been found to cause an increase of temperature and of the vascular tension. Hence its use was contra-indicated in acute inflammatory fevers, but indicated in septic fevers.

As to the form of iron to be used in any given case, that must depend to a great extent on the peculiar conditions existing. The preparations that he preferred were the lactate, the hypophosphate, the subcarbonate, the tincture of the chloride, and the syrup of the iodide. The last-named preparation fulfilled two indications, and was of service particularly in diseases of the glands and of the lungs. One advantage that it possessed was that it was easily decomposed, and the result was the setting free of the iodine, which acted as an admirable corrective of fermentation. The lactate was useful especially on account of its not interfering with digestion, and the subcarbonate was also a valuable preparation. Larger doses of this preparation could be given than of any of the others, and to a child of two years of age should be given from four to eight grains a day. Combined with three times this quantity of bismuth and a much larger amount of bicarbonate of soda, it was very serviceable in anæmia accompanied by gastric irritation. The tincture of the chloride was the one among the ferruginous preparations which was regarded as a vascular irritant, and it was the one mainly indicated, therefore, in conditions of low vascular tension. When there was catarrh of the stomach the pyrophosphate was perhaps the best preparation. Chronic anæmia was far more common than acute, and in this the various preparations in turn could usually be employed with advantage. After speaking of transfusions of blood in general, he alluded to the simple method which had recently been resorted to with apparent success, namely, the withdrawal of blood from the veins of a healthy individual and the direct injection of it into the veins of the anæmic sub-

ject by means of the ordinary hypodermic syringe. As regards the ease with which it could be performed, it had manifest advantages over the more complicated procedures usually adopted, but more experience with it was required to establish it on a firm basis.

Other medicinal agents besides iron were frequently of service, especially in chronic anemia, and one of the best of these was arsenic. To a small child one drop of Fowler's solution might be given three times a day after eating. It was of special service in cases in which there was a peculiar torpid condition of the stomach, due to deficiency both of the gastric juice and of nerve power.

Strychnia was also a useful adjuvant to other measures, and might be given to the amount of one fortieth of a grain to a child two years of age. Phosphorus could be given in about the same doses, and was particularly indicated in all cases where there was any disease of the bones. For several years he had been in the habit of prescribing phosphorus in caries and other bone affections, and he had found that it was of decided benefit. Thus, cases such as formerly took years in which to run their course now did so in as many months, if systematically treated with phosphorus. From one one hundred and fiftieth to one one hundredth of a grain might be given three times a day.

In a large number of cases cod-liver oil was of the greatest service, but there were some contra-indications against its use which were apt to be overlooked. Thus, most children did not bear it well in summer time, as at this season it was apt to occasion gastric irritation and diarrhoea. Some children, indeed, did not bear it well at any time, and in such instances other agents had to be substituted for it. In a great many cases, however, some preliminary treatment had to be gone through with before the little patient was in a condition to take either cod-liver oil or iron with advantage.

QUARTERLY MEETING OF THE RHODE ISLAND MEDICAL SOCIETY.

THE regular quarterly meeting of the Rhode Island Medical Society was held in Providence, December 15th, eighty-five Fellows attending.

Herbert Terry, M. D. Harv., of Providence, was elected a Fellow.

Delegates to state medical societies were appointed as follows: Maine, G. W. Jenckes, of Woonsocket, G. H. Stanley, of Pawtucket; New Hampshire, C. W. Fabyan, of Providence, J. O. Whitney, of Pawtucket; Vermont, Ariel Ballou, of Woonsocket, R. H. Carver, of Providence; Massachusetts, E. T. Caswell and W. R. White, of Providence; Connecticut, T. W. Perry, and A. G. Browning, of Providence; New York, S. W. Butler, of Newport, G. D. Hersey, of Providence; New Jersey, W. H. Palmer, of Providence, W. J. Burge, of Pawtucket.

Dr. C. H. Fisher exhibited a series of ingeniously carved splints, devised by Dr. J. W. Smith, of North Scituate, for treating a severe gun-shot wound of the arm, with compound fracture of the humerus extending into the elbow-joint. The case seemed at first to demand amputation, but conservative surgery triumphed, and now, one year after the accident, the patient has a useful arm.

Dr. T. W. Perry reported several cases of syphilis coming under his observation during thirty-five years of practice:—

CASE I. In 1816 a gentleman contracted syphilis and had the usual secondary symptoms. After two years' treatment, he married, and neither his wife nor either of her five children have showed any syphilitic symptoms. In 1863 the patient's hair commenced falling off in spots, leaving the scalp shiny. The alopecia continued, until, in six months, not a hair was left on his body. Otherwise he remains in good health.

CASE II. A young man of twenty years had syphilis of a mild type, of which he was supposed to be cured. He afterwards married, and became the father of eleven children, all but the youngest dying in youth. At the age of forty-seven epilepsy appeared, and at fifty he died from falling on a stone pavement during a convulsion. A post-mortem examination revealed a node growing from the inner table of the calvarium and projecting three fourths of an inch into the cranial cavity.

CASE III. A student acquired syphilis at nineteen. Married at twenty-two, thinking himself to be thoroughly cured. Eight children issued. The father developed brain symptoms, and committed suicide at forty-five. The wife had only mild symptoms of contamination, such as losing a fine head of hair. The first child died in a few days, covered with a syphilitic eruption. The second child lived, but was of too feeble mind to be educated. The six other children were sons: one committed suicide at twenty-two; the next is insane; the third died of some brain trouble at twenty-four; the fourth committed suicide at about the same age; the fifth occupies a felon's cell; the youngest is the only one having a tolerably well-balanced mind. In the history of this unfortunate family there was no hereditary vice other than syphilis.

In the discussion following Dr. Perry's paper reference was made to the possibility of communicating syphilis by vaccination. Admitting that there is a risk of syphilis when humanized virus is used, the following points were insisted on:—

- (1.) Pure vaccine lymph produces only vaccinia, and cannot transmit any other disease.
- (2.) The use of genuine bovine virus is safest and always preferable.
- (3.) If humanized virus is to be employed, take the pure lymph on the eighth day, free from contamination with pus, blood, or cutaneous secretions, but never from suspected children.
- (4.) The practice of vaccinating heifers with humanized virus, and selling the lymph thus secured for genuine bovine virus, if perpetrated, is an imposition on physicians and endangers public health.

Dr. L. F. C. Garvin defended the use of the metric system in writing prescriptions, and with a blackboard illustrated the translation of the familiar apothecary weights into metric equivalents.

Dr. George Capron read an essay on the use of obstetric forceps, particularly in lingering labor; advocating the use of the long forceps in preference either to turning or craniotomy.

Dr. E. B. Eddy presented a paper on Disease of the Prostate.

Dr. Ely believed rectal examination to be superfluous in diagnosing this affection. Residual urine, detected by passing a catheter immediately after micturition, is sufficient evidence.

Dr. Caswell deprecated the use of force in passing catheters. These cases must be approached with great gentleness, and different cases require different methods

of procedure. Lately, Dr. Caswell saw a case which defied all attempts at catheterization until he tried a soft metallic catheter bent nearly into a circle. In most cases three times a day is too often to introduce a catheter. Better pass the instrument once daily and wash out the bladder, using hydrostatic pressure in preference to the syringe.

Dr. W. O. Brown recommended the use, in these cases, of a flexible woven catheter bent in a large curve, as described by Dr. Squire in *American Journal of Medical Sciences*, July, 1876.

Dr. Greely had uniformly succeeded in surmounting prostatic enlargement by using Mercier's elbowed catheter.

Recent Literature.

Photographic Illustrations of Cutaneous Syphilis. By GEORGE HENRY FOX, A. M., M. D., etc. New York: E. B. Treat, No. 757 Broadway. Price of each number [four plates] \$2.00.

This valuable atlas of plates representing the various syphilodermata is to consist of forty-eight specimens photographed from life and colored by hand. The first three numbers have just been received and are therefore noticed together. The atlases of Devergie (1826), of Ricord (undated, in hope of immortality), and of Cullerier, reproduced 1868, in this country, by the late Dr. Bumstead, hardly meet the requirements of to-day in this important branch of medicine, and we welcome this new-comer both for its own merits, and as a representative of the enterprise of American physicians, who, in the field of dermatology, are pressing hard after their German forerunners, and developing its practical, as those its scientific relations.

The narrow-minded and short-sighted policy of excluding syphilitic patients from our hospitals, and leaving them to spread disease through the community, prevents both students and physicians from becoming acquainted with the objective aspect of the syphilodermata, and good illustrations as well as descriptions are consequently imperatively demanded. Photographs colored by hand, however, require the greatest care in their treatment if they are expected to equal some of the superb chromo-lithographic representations of diseases of the skin hitherto furnished, and we notice that the same plates in different fasciculi possess varying degrees of merit, though all are quite good. The first fasciculus contains four quarto plates prepared by the artotype process, representing erythematous syphilis with the pigmentation and leucoderma which may follow the disappearance of a syphiloderm. These are excellent, the delicate tinting reproducing admirably the non-pronounced character of the lesion as to color.

The second fasciculus is composed of four plates portraying, respectively, lenticular, miliary, squamous, and papular syphiloderms. These also are highly creditable to the artist. The first and second, of necessity, have a slight tendency to pictorial development; the third attempts, with commendable but not perfect success, as difficult a task as there is, perhaps, namely, the accurate imitation of scales in relief; the fourth is typical and admirable.

The four illustrations in the third number are different from those given in the provisional list of what might be expected. They consist of I., syphilodermata

papulosum circinatum, which is very good; II., S. papulo-squamosum, open to the criticism already made above; III. and IV., S. papulo-pustulosum, the former more papular, the latter more pustular, and both well executed, but needing no special encomium or disparagement.

In the text accompanying these illustrations "the aim has been to present a practical exposition of the subject with special reference to points of diagnosis and treatment," and the writer has hit the mark.

E. W.

A Manual of Medical Jurisprudence. By ALFRED SWAIN TAYLOR, M. D., F. R. S. Eighth American edition from the tenth London edition; edited by JOHN J. REESE, M. D. Henry C. Lea's Son & Co. 1880. Pp. 933.

A special interest attaches itself to this book in the reflection that it is in a literal sense the last edition of its distinguished author's work; he had hardly completed the revision, whose fruit we possess in this new volume, when his death occurred, occasioning a loss to forensic medicine which may rightly be described as irreparable. It is said that Professor Taylor's lecture room was not an attractive one to medical students, but, fortunately for forensic medicine everywhere, his teaching has not been limited to the few who have attended the exercises within the gray walls of Guy's, and the numerous host of lawyers and physicians, who, since 1844, have confidently appealed to this manual to aid them in the resolution of difficult questions in all departments of medical jurisprudence will regret that the master's ripe and comprehensive experience is withdrawn, and that his work must henceforth be revised by other hands. It is surely unnecessary to present any minute analysis of the merits of a book so well and so favorably known as Taylor's Manual, or to indulge in any critical comments upon its characteristics; a review of Webster's Dictionary would be hardly more impertinent. It will suffice to remark that this new edition shows the signs of judicious revision. A great number of illustrative medico-legal cases which have occurred since the last edition was published are cited in their proper connection, and add much to the interest and value of the work; they comprise the bulk of the additions to the text. As an indication of the freshness of the work, we notice numerous references to medico-legal experience that has transpired during the year just ended; among these is a comment by the American editor upon that midsummer madness, the Tanner fasting exploit of last August. In these features and in others there is ample evidence that this admirable book will maintain its high place as a standard authority concerning the matters of which it treats.

On Slight Ailments: Their Nature and Treatment. By LIONEL S. BEALL, M. B., F. R. S. Philadelphia: Presley Blakiston. 1880. Pp. 353.

The name sufficiently indicates the purpose of the book. The author believes that most students of the present day graduate with too little knowledge of the minor ills, and wishes to show the importance of listening to patients' complaints and relieving their pains,

even when the pathological lesion is of little importance. The book embodies the substance of a series of lectures, and preserves something of the original style, though not the original form. The main portion of the book treats of the derangements of the stomach and bowels, though, as every one familiar with Dr. Beale's books on the microscope can imagine, a great deal of somewhat irrelevant but very interesting matter is incidentally introduced. The doctor has a firm belief in the efficacy of mercurials, and has a good deal to say about "biliousness," though he confesses himself unable to give a satisfactory definition of the term.

In speaking of constipation the author places his erities in an unpleasant position. "Many a severe article would never have seen the light if the critic's large bowel had been in good order at the time. Any of you who desire to excel in this department of literature cannot do better than cultivate indigestion and other derangements of the bowels." The directions for the medication of dyspeptics leave much to be desired. Though several courses of treatment are given, they are left for hap-hazard application.

The remaining subjects treated are Neuralgia and Rheumatism, the Feverish and Inflammatory State, Actual Changes in Fever and Inflammation, and Common Forms of Slight Inflammation.

It is hardly possible for any one to read the book without finding something with which he will fail to agree. Few, however, can fail to find something to profit by, and the book must lead every one to look more carefully after his minor cases, and to trace their connection with the severer forms of disease.

Ophthalmic and Otic Memoranda. By D. B. ST. JOHN ROOSA, M. D., etc., and EDWARD T. ELY, M. D., etc. Revised edition. New York: William Wood & Co. 1880.

Many parts of the book have been rewritten and some thirty pages of new matter selected. The authors repeat in their preface "that the work is rather a dictionary of Ophthalmic and Otic Science than a text-book; that it gives only a bare outline of the subject of which it treats, and that it is never to be recommended as a substitute for the larger works." If these warnings are heeded the little book may be of value. The danger is that it may be employed in a manner opposed to the advice given. For a work of its sort it is exceptionally accurate.

Atlas of Skin Diseases. By LOUIS A. DUNNING, M. D., etc. Part VIII. Philadelphia: J. B. Lippincott & Co. 1880.

Of the twelve numbers which are to compose the admirable atlas of Dr. Dunning eight parts have now appeared. The eighth fasciculus maintains the high standard of the previous ones. It comprises plates of erythema multiforme (papulosum); psoriasis; syphiloderma (tuberculosum); and tinea trichophytina (circinata et tonsurans). All are excellent. The second gives a delicate type of the disease, such as may appear upon anemic people, and one not furnished by most atlases. In the third plate the appearance of a few of the lesions, to be perhaps hypercritical, is somewhat too superficial, erythematous and, as it were, superimposed upon the skin, to represent the usual

normal syphilitic tubercle. Others are, however, capitally represented. As a whole these plates portray with great exactness the diseases as seen in practice. The text is clear and concise, and what we should expect from our leading writer upon dermatology. The press work is unimpeachable. The work as a whole will be priceless and should be possessed by every physician.

Treatise on Therapeutics. Volume III. By A. TROUSSEAU and H. PIDOUX. Ninth edition. Revised by C. PAUL, and translated into English by D. F. LINCOLN, M. D. New York: Wm. Wood & Co.

This volume completes the treatise. We have little to add to the criticisms on this translation which were referred to in the JOURNAL of a few months ago. The revisers of Trousseau's work have given us only trivial information in reference to the new drugs recently introduced to the medical profession, as illustrative of which criticism we refer our readers to the articles concerning jaborandi; and no mention has been made of salicylic acid and other familiar modern medicines. In view of these and other similar omissions it is rather a matter of regret that any pretended revision has been attempted, and that Trousseau's original text was not strictly adhered to. A partial revision has not materially improved this work when it is compared with the more modern treatises on therapeutics.

Yellow Fever: Its Ship Origin and Prevention. By ROBERT B. S. HARGIS, M. D. D. G. Brinton, M. D. Philadelphia.

This thin volume consists of three papers, reprinted from medical journals, on The Ship Origin of Yellow Fever, Practical Hints relating to Yellow Fever, and The Most Recent Utterances on Acclimatization and Endemicity. To these articles are appended two letters from Professor John Gamgee, — a short one addressed to the author, and a longer one to Rear-Admiral Ammen on the Inter-Oceanic Ship Canal and the Yellow Fever Law. Dr. Hargis thinks that no opinion could be sustained with more irrefragable evidence than that yellow fever originated in foul ships. He thinks, moreover, that under an adequate central administration by a medical board this disease "can be stayed, and extinguished for all future time from the bloody annals of controllable epidemics." In the course of his remarks the author pays his compliments to "obnoxious quarantines" and to Dr. Chaillé, of the Havana Yellow Fever Commission.

Clinical Lectures, and Cases with Commentaries. By HENRY THOMPSON, M. D., etc. Consulting Physician to the Middlesex Hospital. London: J. & A. Churchill. 1880.

Most of the papers composing this octavo volume of 200 pages appeared originally in the London journals, or in the Transactions of the Clinical Society of London. In general they are reproduced with few variations from the original form, and the author offers them as a legacy — *in memoriam* — to the Middlesex Hospital rather than to the public. Sixteen clinical lectures and twelve cases with commentaries make up the table of contents.

Medical and Surgical Journal.

THURSDAY, JANUARY 13, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, Boston, Mass.

THE ACTION OF ANESTHETICS.

At its meeting in 1877 the British Medical Association appointed three gentlemen of Glasgow a committee to investigate the action of anesthetics. They have already published three preliminary reports, and now print a detailed account of their work from the date of their appointment to the present time, giving tables, diagrams, pulse and respiration tracings, and figures of instruments used.

The particular objects of study which the committee proposed to themselves were to discover wherein the special dangers of chloroform consist, and to seek for some anæsthetic agent which would avoid these dangers; though the physiological action of anesthetics in general and the collection of clinical evidence in regard to their value and their dangers have also been kept in view.

In seeking for a new anæsthetic various substances which, from their composition, it appeared possible might prove efficient were experimented with. Of these *ethidene dichloride* was selected as the most promising. It had already been occasionally used, and was the subject of one of the preliminary reports above mentioned; since then it has been tried somewhat extensively in England, and Mr. Clover has reported a series of nearly nineteen hundred cases. After the selection of ethidene, the work of the committee has been in great measure the comparison of the action of chloroform and ethidene, with occasional references to ether. The clinical investigations were very carefully made in the wards of the Glasgow Western Infirmary, and two tables are printed, each of fifty cases, of chloroform and ethidene narcosis, showing time, relations, etc. The result showed that anæsthesia was more rapid with the new anæsthetic. The average time necessary to produce insensibility with chloroform was 5.4 minutes, with ethidene 1.3 minutes. No similar table of ether narcosis is given, which we greatly regret, as we feel sure that it would have somewhat modified the opinion of the committee; for there runs through the report the scarcely expressed idea that ether is altogether too slow for practical use. After spending twenty minutes in producing insensibility in a rabbit, "the tardiness of its action" seemed fully established.

The susceptibility of patients to ether varies very greatly, much more, apparently, than to chloroform; some yield to its influence very readily, while others resist to a remarkable degree. Practice and tact are great assistants to its rapid administration, and a previous training with chloroform does not seem to be

the best preliminary to its use. A sentence from an article in the Royal Medico-Chirurgical Transactions for 1872 seems worthy of quotation here, as showing that one gentleman at least has been able to overcome the difficulties: "The chief objection that has been made to ether is the greater quantity and therefore longer time required to render a person insensible. This does not appear to me a very powerful objection, and, moreover, by attention to a few simple matters insensibility can be produced almost as rapidly as by chloroform." Certainly since the utilization of the "primary narcosis" in minor operations, the objection to ether on the score of time is greatly diminished.

The faithfulness with which the committee have stuck to their appointed line of work, and how little they have allowed outside events to distract their minds is shown in the schedule of Future Studies; they "hope to get specific information from America, as they have found it impossible to get cases of ether administration in this country sufficiently numerous for the purposes of comparison," to which is appended the note, "They were not aware at the time of writing this report that the use of ether is rapidly making way in this country, and that it is now solely used in several large provincial hospitals."

The exceedingly interesting details of the long series of scientific experiments we are obliged to pass over, and must content ourselves with a consideration of the committee's conclusions, some of which we shall quote in full, as putting upon a scientific basis the views advocated by the JOURNAL for a long series of years. It would be interesting but hardly necessary to quote them all *in extenso*.

The case against chloroform, as summed up by the committee, is even stronger than its severest critics have ever claimed; not only is its depressing action on the heart established, but it is shown occasionally to act primarily upon the respiration, and furthermore, in two cases in animals, its sudden and unlooked-for effects on the heart's action occurred more than a minute after the cessation of its administration. (In Taylor's Medical Jurisprudence a case is given in which the heart suddenly ceased to beat four minutes after the vapor had been withdrawn). On the other hand careful experiment showed that ether has no primarily depressing effect upon the heart at all.

From the practical conclusions we quote the following:—

(1.) It is not only necessary to watch the effect of the anæsthetic upon the pulse, but it is also requisite to have regard to the respiration. We must not only take into account the danger of sudden stoppage of the respiration, but must also remember that, in the event of abnormal increase of respiratory movements, it may become essential, for the safety of the patient, to temporarily discontinue the administration.

(2.) Owing to the tendency of chloroform and ethidene—particularly chloroform—to reduce the blood-pressure suddenly, not only during the administration of these agents, but also after they have been stopped for some little time (a source of serious danger), it is necessary for the person who has charge of the administration of the drug to be on the lookout for symptoms of this occurrence, both during the time the agent is being given, and for some time after the patient has recovered from its more evident effects.

(3.) As regards comparative danger, the three anæsthetics may be arranged in the following order: chloroform, ethidene,

ether; and the ease with which the vital functions can be restored may be conversely stated, thus: the circulation is more easily reëstablished when its cessation is due to ether than to ethidene; and when the result of ethidene, than when chloroform has been used. The advantages which chloroform possesses over ether—in being more agreeable to the patient, and more rapid in its action, in the complete insensibility produced by it, and the absence of excitement or movement during the operation—are more than counterbalanced by its additional dangers.

(5.) The chief dangers are: (a) sudden stoppage of the heart; (b) reduction of the blood-pressure; (c) alteration of the pulse-respiration ratio; and (d) sudden cessation of the respiration. The danger with ether approaches from the pulmonary rather than from the cardiac side—so that, by establishing artificial respiration, we have a means of warding off death. Its disadvantages are, to a great extent, obviated by the use of ethidene; whilst the dangers of chloroform are also reduced to a minimum.

We wish to draw attention to the fact that ethidene is shown to possess the same inherent tendency to depress the heart as chloroform, though in a less degree. It certainly is not sufficiently free from danger to allow it to supplant ether in its claim to be the safest of known anæsthetics, and we beg to quote and emphasize the warning of Mr. Clover, whose experience in the practical use of the drug is probably greater than any other man's. "It must never be forgotten that it (ethidene) cannot be used with the same freedom as ether may be."

The committee have evidently failed in their first object, the discovery of an anæsthetic "as potent as chloroform which should affect heart and respiration as little as ether," but it has done most valuable work and produced perhaps the most valuable contribution to the voluminous literature of the subject. Nothing that has been said should be construed as detracting in any way from the value of their services. We sincerely hope the Scientific Grants Committee will authorize the continuation of their investigations.

The same number of the *British Medical Journal* which contains the report gives also the promised lists of deaths during anæsthesia in England for the past eleven years. The chloroform list contains one hundred and twenty, the ether eleven cases. Both lists, as the *Journal* shows, contain cases which cannot fairly be counted against either drug.

The chloroform list contains four cases of self-administration. In at least three others death was due to suffocation from foreign bodies in the trachea.

Of the ether cases one was anæsthetized with Robins' "anæsthetic ether," a compound of ether and hydrate of amyl. Three were cases of advanced intestinal obstruction. One was suffocated by blood in the trachea, and one died apparently of fright within two minutes of the commencement of the administration. What facts a careful examination of the original accounts of the other cases would develop we do not know.

The *Journal* seems to imply a censure for the imperfect manner in which cases of death during operations are reported in England, and even that certain cases are not reported at all. Conversely its words ought to imply the highest praise for the few men who have courted publicity in similar cases.

Additional lists of methylene, and "mixed vapors" deaths are given.

PROLONGED LATENCY OF HYDROPHOBIA.

At the séance of the Académie de Médecine, November 2d last, Prof. Léon Colin, of the Val-de-Grâce hospital, brought to the attention of his colleagues a case which he felt compelled, though reluctantly, from the evidence to regard as one of hydrophobia, in which the disease had an incubation of four years and ten months. The unfortunate victim was bitten in Algeria, November 2, 1874, whilst succoring a companion from an attack of a mad dog; the companion died in forty-eight days. The subject of Professor Colin's report, a non-commissioned officer in the French army, was decorated for his act of devotion, and survived the incident in good health until the 9th of August, 1879, when he began to exhibit the usually accepted symptoms of hydrophobia, and died two days later. The autopsy failed to reveal any lesion which could account for death.

Professor Colin's statement of the case leaves scarcely any doubt in the mind that the disease was hydrophobia. A careful investigation could not discover any other source of infection than that in Algeria five years previous to death.

The other soldier concerned in the Algerian incident was not cauterized until the day following the receipt of the bite, and died, as we have said, in forty-eight days; Lechenet, Professor Colin's patient, was cauterized thoroughly within half an hour. In both cases the hot iron was used.

The event made a marked impression upon Lechenet's mind, and during his final sickness he frequently referred to it as the cause. He was a steady man, of good habits, and the investigation into his past history was facilitated by his continued service in the army.

Professor Colin's report was discussed at the next meeting of the Academy, November 9th.

M. Bouley, whose name is widely known in connection with government reports on rabies and hydrophobia, objected that the case might, perhaps, have been one of *hydrophobie nerveuse*, that the diagnosis had not been assured either by the search for and discovery of leucocytes in the perivascular spaces of the medulla, or by the inoculation of rabbits with the virus, these animals, as shown by M. Galtier, of Lyons, being extraordinarily susceptible to the poison, and the incubation of the disease in them only requiring fifteen days. He objected, moreover, that though the disease were hydrophobia it might easily have had some other origin than the bite received in Algeria. M. Maurice Raynaud, on the other hand, stated, as is the general opinion, that the presence of white blood corpuscles in the perivascular spaces of the neighborhood of the fourth ventricle is by no means pathognomonic of hydrophobia. M. Bouillaud supported Professor Colin's view of his case.

The case is evidently not susceptible of absolute proof, but it is certainly not philosophical to reject evidence which would otherwise be accepted, simply because it leads to astonishing conclusions. As we remarked three years ago, when discussing this same subject, volume xcvi., page 182, there is no more

difficulty in accepting an incubation of years than of months. It is true that out of three hundred and thirty cases of hydrophobia, selected from the French returns, as carefully reported, there is not one in which the incubation was prolonged beyond twelve months; out of two hundred and twenty-four carefully recorded cases, between 1850 and 1862, of these French government reports, there were only eleven with an incubation of over six months; and out of one hundred and six carefully noted cases, between the years 1863 and 1868 inclusive, the period covered by the report of M. Bouley, there was only one case in which the time of incubation covered eight months; in all the rest it was less than six months.

Professor Colin cites, on the contrary, two cases, we know not how authentic, the one preceded by a period of "latency," as he prefers to term it, of two years and five months, and the other of two years and a half.

We share the opinion of Professor Colin that it is proper and for the public advantage that such cases should be reported, but only after due delay and thorough study of the facts.

A REAL KNOWLEDGE OF INSANITY AND ITS TREATMENT.

IN an editorial article published in the *JOURNAL* May 20th last, volume cii. page 497, expression was given to a feeling of dissatisfaction with the composition of the then existing lunacy department of the Massachusetts Board of Health, Lunacy, and Charity, on the ground that, whatever their other qualifications might be, no one of that department possessed a real knowledge of insanity and its treatment.

This criticism passed unchallenged for more than six months, when exception was suddenly taken to it. We therefore feel it proper, though at this late day, to define somewhat precisely our idea of the requisite training for the obtaining of a real knowledge of insanity and its treatment, as this will, perhaps, best define in what that knowledge consists.

A thorough general medical education is an indispensable preliminary to such training; these studies should be followed by some years of experience in general private or hospital practice, and the final pursuit of the special branch of insanity must be founded upon and accompanied by personal observation and treatment of the disease as a medical officer in the wards of an asylum.

Doubtless it is possible for a stupid or a lazy person to have had access to all these desiderata and yet escape the possession of a real knowledge of insanity and its treatment, but without this training we hold that such knowledge is not to be found. A person may know something about insanity and the insane, have a great and in some ways valuable acquaintance with the statistics of the disease and the sociology of the afflicted, and yet not possess a real knowledge of insanity and its treatment. We hold it to be of the first importance that such a real knowledge should be

not only represented, but strongly represented in any department of lunacy, or on any lunacy commission, as is the case in the Scotch and English commissions. There would still be plenty of room left for executive or administrative capacities. Just as we are opposed to the superintendent of an asylum being made a mere administrative factotum, so we are opposed to a department in lunacy being made a mere machine.

KOLPOECPETASIS. II.

IN his early experience Dr. Bozeman employed almost exclusively bags of oiled silk filled with compressed sponge, but of late years, owing to the trouble of having to renew these bags every two or three days while the treatment was in progress, he has employed instead hard rubber made into the required shapes and sizes, which of course is unaffected by the urine. For ready use, however, he still believes that cylinders of compressed sponge, made in the way indicated, are equal, if not superior, to any other known form of vaginal dilators, for the reasons that they are soft, elastic, uniform in pressure, and, when properly attended to, unirritating to the healthy and diseased tissues with which they come in contact.

The great advantage claimed for this intra-vaginal dilatation is that it can be increased by degrees to a point far beyond the limits of vulvo-vaginal dilatation, at which the power of the patient's endurance ceases; it being possible thus to carry it from one to two centimeters further than by the most extensive dilatation of the latter character. Intra-vaginal dilatation can be continued until resilience is completely overcome, as in the male urethra; but if this is attempted by means of the vulvo-vaginal dilatation, the patient is often unable to stand the very severe pressure thus brought to bear upon the perineum and the pelvic arch, while there is besides great danger of the urethra's sloughing.

But, in order that complete success may be achieved in any instance, the author lays stress upon the importance of carrying out his other methods in addition to kolpoecpetasis. Thus, the patient should be placed in the knee-chest position,¹ because this is believed to be the one above all others from which the greatest number of advantages can be derived, as regards relaxation of the abdominal muscles, gravitation forwards of the abdominal and pelvic viscera, natural relationship of the affected parts, direct rays of light, and adaptability for the use of instruments, while fixation and anaesthesia of the patient upon a suitably constructed support or chair are essential to the full realization of the advantages named.

Again, he holds that long, narrow, dilating lateral

¹ More than a quarter of a century ago Dr. Bozeman began to advocate this position (not the exaggerated knee-elbow position, to which the designation has so often been applied), as the one in which the greatest success in any operation for vesico-vaginal fistula was to be secured, and, as may be seen from his numerous publications since upon this subject, he has not abated in the slightest his opinion of its value, only as he has modified and improved it as shown by his operating or supporting chair, adapted expressly to the "right-angle position upon the knees and chest." (See *New York Medical Journal*, February, 1869.)

blades and a short, movable perineal elevator are the means from which the greatest limit of transverse vulvo-vaginal dilatation and the greatest amount of light are to be secured, with the least obstruction in the field of operation, and that a speculum combining these elements, and having a self-sustaining action by virtue of the flaring expansion of the lateral blades, with a system of leverage which gives increased power with increased resistance (as claimed for the Bozeman speculum), is far preferable to any system of separate or detached blades held by assistants, since the surgeon, with this instrument, can easily develop or put upon the stretch any resisting cicatricial tissue, wherever and whenever found in the vaginal tract, by simply turning the thumb-screw.

Finally, it is claimed that in operating upon a fistule the borders, when refreshed and drawn together with the proper number of silver wires, require to be held in the same stretched and even relationship as at the instant when the dilatation is discontinued and the operation commenced, and that to accomplish this and guard against subsequent recontraction of the vaginal tract at the seat of the old stenosis (the great obstacle to primary and permanent union between the edges of the fistule), it is necessary to supplement the sutures with a vaginal splint of sheet lead, secured over the coaptated edges of the fistule by means of compressed perforated shot upon the doubled sutures. The indications fulfilled by it are claimed to be as follows: (1) permanent maintenance of the borders of the fistule in a stretched and smooth relationship during the healing process; (2) fixation by the sutures of the borders of the fistule to the under surface of the button or splint in short and regular divisions; (3) uniform support of both borders of the fistule in each division of the splint, by which is preserved free circulation of the blood and nutrition in the parts otherwise liable to be cut off or impaired by the intensity of the retractive forces; (4) diminution of direct traction upon each suture to the extent of at least twenty-five per cent.; (5) control of all motions in the included borders of the fistule, on the principle of well-adjusted splints and bandages to a fractured bone after the limb is reduced to its proper length; (6) exclusion from the entire line of the coaptated edges of the fistule of all extraneous influences, atmospheric as well as those of vaginal and uterine secretions. When this method is used, it is said that with one half the number of sutures one third greater resisting power can be obtained than with the Sims suture. When the latter is employed there is often great danger of sloughing on account of the low vitality of the kind of tissue met with in these operations; but this is avoided with Bozeman's, because the sutures being much less numerous, the circulation is not interfered with. The worst that can happen is that the sutures may possibly tear out. When the supradilatation of the vagina recommended by Dr. Bozeman is practiced, it is very difficult to get the Sims' suture to hold, on account of the extreme thinness of the edges, but with this button suture it makes no difference whether the edges are thin or not.

Enough has now, perhaps, been said to give some idea of the methods which Dr. Bozeman has devised, and which he is constantly employing in his public and private practice. If it is true, as he contends, that so much needless suffering can be prevented, and even lives saved, by resorting to them, it is certainly desirable that they should be more generally adopted, and the object of this article will have been attained if any of those who are interested in such subjects should thereby be induced to make trial of them, so that the matter can be thoroughly tested, and the claims now set forth either substantiated or disproved.

MEDICAL NOTES.

— We hope that those of our readers who have not subscribed for the *Index Medicus* for the coming year, and feel able to, will do so. Though true that one copy in a library is sufficient for the purposes of reference, this way of viewing the matter will not support the undertaking.

— There is, and has been for some time, a great deal of small-pox in Philadelphia, and the deaths from it are steadily and alarmingly increasing, as may be judged by the following statement: Deaths for the week ending November 6, 1880, 22; November 13, 18; November 20, 20; November 27, 25; December 4, 32; December 11, 26; December 18, 40; December 25, 38; January 1, 1881, 53. Such a state of things offers a constant menace to the whole country.

— On the 28th of December the thirty-fourth case of cremation occurred at Gotha.

— The *Louisville Medical News* will hereafter be under the editorial care of Dr. R. O. Cowling, Dr. L. P. Yandell having retired from his position as associate editor. Dr. H. A. Cattell assumes the position of managing editor. It is a bright, original, and independent publication, and we doubt not will continue to be what it has been.

NEW YORK.

— The new building of St. Mary's Free Hospital for Children is just completed. It has a frontage of fifty feet on Thirty-Fourth Street, and is sixty-five feet deep, with an addition extending back from the main structure thirty feet long by nineteen wide. It is constructed in a substantial manner, finished mainly in ash, with hard pine floors, and it is thoroughly heated by steam, with direct and indirect radiation. In the basement are the reception ward, dispensary, drug and store room, kitchen, and laundry departments. The first floor is occupied by a ward, reception room for visitors, office, and dining-room; the second floor is devoted to hospital purposes; on the third floor are the Sisters' sleeping-rooms, linen room, etc.; while the fourth floor contains the operating room, children's play-room, and servants' sleeping-rooms. The isolation ward is on this floor, in the extension, and is completely cut off from the rest of the house. Each ward has connected with it a

dining-room. All the plumbing is done in a substantial manner, and is in the extreme end of the extension, while the pipes are all left exposed, both for cleanliness and easy access. The hospital can accommodate about seventy patients.

— The contributions on Hospital Saturday and Sunday (Christmas and the day following) are said to have been very much larger than last year, the methods and design of the collection being more fully understood and appreciated by the public than when the experiment was first tried. Boxes for contributions were placed in all the ferry-houses, railway depots, hotels, club-houses, restaurants, armories, and drug stores, and collections were taken up in all the synagogues and churches on Saturday and Sunday; while most of the street cars and omnibuses had the yellow hospital flag flying to remind the general public of the occasion. In addition, many of the business exchanges and trade organizations appointed special committees for securing subscriptions among their members, and all of these committees report amounts largely in excess of those obtained last year. Thus, the Cotton Exchange contributes \$1200 as against \$185 last year, and the Produce Exchange \$1300 as against \$700 last year. The Rev. George S. Baker, of St. Luke's Hospital, who is secretary of the general committee having the matter in charge, states that the amount collected will probably reach \$50,000, or nearly double the sum raised last year, which was about \$26,000.

The fund will be divided on the plan adopted last year by the Hospital Saturday and Sunday Association, according to the charity work and the needs of each, among the various hospitals uniting in the movement, which are as follows: St. Luke's Hospital, St. Mary's Free Hospital for Children, Roosevelt Hospital, Mt. Sinai Hospital, Presbyterian Hospital, New York Infirmary for Women and Children, the Orthopaedic Hospital, New York Eye and Ear Infirmary, the German Hospital, Manhattan Eye and Ear Infirmary, New York Hospital, New York Ophthalmic Hospital, Institution for Relief of Ruptured and Crippled, House of Rest for Consumptives, the Woman's Hospital, the Home for Incurables, the Nursery and Child's Hospital, and the Hahnemann Hospital.

Mr. Lester Wallack will give the gross proceeds of a benefit at his theatre some afternoon in January to the fund, and several other theatrical managers have signified their intention of giving benefits for the same purpose.

— The plan of conducting a seaside house in the warm weather in connection with St. Mary's Hospital, which had been begun the previous year, was continued during the past summer, a house at Far Rockaway being hired for the purpose. In this the Sisters were able to accommodate about thirty children at a time, and from the first of May until the middle of September the building was kept filled with little ones gathered from the tenement population. In this way one hundred and twenty children were given at least two weeks at the seaside, while others, who were more feeble, were kept longer. The expense of maintain-

ing this department was defrayed out of the "Fresh Air Fund."

— Dr. J. Marion Sims, who has been very seriously ill with pneumonia, is reported as now improving.

— In the legislative inquiry into insane-asylum management in New York, which commenced on the 1st of December, and which was recently alluded to in the JOURNAL, the following was some of the testimony elicited:—

Dr. Edward C. Spitzka said that he agreed with those who believed that the fault in asylum management, as at present conducted, lay in the system. The boards of trustees, being of local character, were not responsible to any central authority for the performance of their duties, and, as they were generally laymen, it was not to be expected that they would properly judge of the qualifications of those appointed to medical and other positions in the asylums. It was true that there was a commissioner of lunacy, and on the face of the law it would seem that he had the general control of the management of the asylums of the State; but even if he were willing to do his duty, he would be hampered by the contradictory clauses of the law regarding him. The result of the law had been that the commissioner of lunacy was neglectful of his duties; for even if he could not have corrected abuses, he might at least have called attention to such abuses as, in the capacity of an expert, he should have discovered. The present commissioner's standing as a scientist, however, had been repeatedly questioned on the other side of the water, and he had been severely criticised by Foville, one of the most eminent authorities. Dr. Spitzka then gave a number of instances of abuses in asylums which had come to his notice.

Dr. William A. Hammond was the next witness. After commenting upon the manner in which medical appointments were made in the asylums, the generally insufficient qualifications of the applicants, the forcible feeding of lunatics, the disposition of letters written by patients, he stated that the whole system of the management of the insane was wrong. The office of superintendent should be abolished. There should be lay superintendents to do their duty, namely, to lobby in the legislature, raise turnips, receive visitors, and entertain the state commissioner in lunacy when he made his rounds. The superintendent should be merely a steward, and there should be medical officers, just as in other hospitals. The law should be changed in regard to allowing the commitment of a person to an insane asylum on the affidavit of two physicians whether or not it was dangerous for him to go at large. The old law provided that a statement should be made in the affidavit that the lunatic could not be permitted to go at large, but the new one did not. Consequently, the asylums were filled with people who had no business there, and who would be better cared for at home. There should be some system for the employment of lunatics in the asylums, as was the case in Europe. At present there was almost none in this State, except in the Willard Asylum and, to some extent, in that at Poughkeepsie.

Dr. E. C. Seguin testified that he had learned from good sources that the asylums on Blackwell's and Randall's Islands were overcrowded, and that the number of assistant physicians in the institutions was entirely too small. Curable and incurable cases were aggregated instead of being separated. The acute insane should have as many attendants, in most cases, as individuals suffering from ordinary diseases, and he thought it would be a great benefit to the community at large if there were a small hospital for acute cases of insanity within the limits of the city, which could be officered in much the same way as the Bellevue and New York hospitals, for instance. Under this system medical students and young graduates in medicine might acquire a knowledge of insanity. It was sometimes necessary for the medical attendant to restrain a patient; but he considered the necessity exceedingly rare. Straps, the "muff," and camisole were used at Poughkeepsie as a means of restraint, and these things tended to increase the excitement of the patients and the laziness of the nurses. For so large a State as New York there might be three commissioners in lunacy, with a fixed salary; and he was strongly in favor of work for insane patients as a means of treatment.

Dr. L. C. Gray, of Brooklyn, said that under the supervision of the present superintendent of the Flatbush Asylum considerable effort had been made to remedy abuses; but his power was limited. There was an outrageous overcrowding in the asylum, and the proportion of physicians was altogether inadequate, — five to eight hundred patients. The inmates were locked up in wards, and as the institution had insufficient grounds, from the beginning of winter until warm weather set in, the majority went down-stairs very little, or not at all. In ordinary life a physician was not allowed to treat even skin diseases without proper education; but a man might be in charge of hundreds of patients afflicted with diseases that were least understood, when he had had no training whatever for the position. A system of competitive examinations would remedy that abuse.

Mrs. Josephine Shaw Lowell, of the State Board of Charities, after detailing some of the disadvantages under which the city asylums labored, presented the following remedies, which, she thought, would place the New York asylums on a fair footing with others in the State:—

First, let the salaries of superintendents and staffs be paid by the State at the same rate as those paid at the Willard Asylum.

Second, establish training-schools for attendants.

Third, provide for a portion of the patients elsewhere.

Fourth, state commissioners in lunacy to be appointed who should have power to remove superintendents for cause, while the appointing power was retained by the city.

Fifth, as to new asylums, no hospital for the insane should have less than fifty acres of land around it, nor less than one hundred acres for each two hundred patients, and the largest number of patients to be

treated in one building not to exceed two hundred and fifty.

Dr. W. J. Morton stated that at the National Asylum at Washington workshops were established two years ago, and work was given the patients as a reward for good behavior. The good effect upon all the patients had been very marked, and large additional shops were to be established. He considered it infamous that patients alleged to be insane should have to wait from three to ten days before their cases were taken up and decided, or any treatment given them. There should be a city hospital for acute cases and country colonies for chronic cases. In the London Hospital for acute cases fifty per cent. of them were cured, chiefly because the hospital afforded opportunity for immediate treatment.

Dr. T. A. McBride thought the root of existing abuses was in the want of knowledge of insanity on the part of a majority of physicians, and unless the State aided the profession in getting this knowledge by the establishment in cities of hospitals for the acutely insane, under a corps of alienists who should give lectures and clinical demonstrations, he had little hope of much improvement. Asylums for the chronic insane alone should be in the country. Now the two classes were mixed, and many patients were kept insane by association with the insane.

Dr. A. E. Macdonald, superintendent of the Ward's Island Asylum, replied to criticisms which had been made upon that institution by the gentlemen previously examined, and gave a number of details in regard to its management. The assistant physicians, he said, usually remained about a year, and they were mostly young men who went to the asylum for the training which they could get there. They left the institution from time to time to take better positions, and four had gone away during the past year. When he first went to the asylum, six years ago, about forty patients were employed; while at present 373 were engaged in various occupations. About 200 worked on the farm, and, out of 1173 inmates, 1137 had been out-doors the day previously, which was the usual average for a fine day. For each additional attendant allowed him he said he could put fifteen more patients at work. It was not true that restraint and forcible feeding of patients were imposed in the asylum by attendants, without the authority of a physician's order. He believed that restraint should be used as a medicine, and a record was kept of the restraint that was employed. The use of the "crib" had been abandoned, mainly on account of popular clamor, in order that the friends of patients in the asylum might not be unnecessarily alarmed.

Dr. T. M. Franklin, superintendent of the Blackwell's Island Asylum, said that that institution was far from faultless, but that a large part of the defects were those of construction of the building. Restraint was imposed mostly by means of the camisole and, to a small extent, by wristlets. There were also "muffs," and "that much-abused instrument, the crib." There were four cribs in the institution, and he wished there were more. Violent patients were not generally put

in the crib, as their struggles in it would soon exhaust their strength. The absolute abandonment of restraint would not redound to the welfare of such an institution; but there was less restraint now employed in the Blackwell's Island Asylum than had been the case five years ago. About one third of the 1295 patients were employed.

Dr. Allan McLane Hamilton expressed the opinion that the qualifications of the superintendents and assistants in the asylums had been grossly misrepresented, and that in institutions where the system of non-restraint prevailed all sorts of abuses crept in. As to European asylums, he said, a padded room in a model institution at Berlin was found covered with vermin and fetid matter, and the colony system at Ghel had resulted, among other things, in the birth of idiot children.

The Rev. W. G. French, a clergyman in the service of the Protestant Episcopal City Mission Society, testified that the female asylum on Blackwell's Island was so constructed that nurse and attendants were nine tenths of the time out of the supervision of their superiors, and he thought that no deed of cruelty, or wrong, or immorality in these closed halls was beyond belief. If patients complained, the nurses or attendants could give such explanations as they chose, so that the patients would not be believed, and he had seen many such cases in which he knew, or learned afterwards, that the charges made by inmates were entirely true. It was only two years since table cloths, china, and knives and forks had been substituted, through Mrs. Lowell's influence, for the finger-eating barbarism, with tin paws, tin plates, and bare boards, that had been in use before that time.

After some further testimony by Drs. Beard, Goldsmith, and others and a visit to the city asylums, the committee concluded their labors in New York for the present. Their report to the legislature will probably not be made before February.

Miscellany.

SLIPPERY-ELM-ROOT DILATORS.

MR. EDITOR,—I noticed in your issue of October 28th a note in regard to slippery-elm-root dilators for rapid dilatation of the cervix uteri and of the urethra, etc. As I called Dr. Skene's attention to their use, and as your note fails to convey any definite idea as to how they are made, I thought a fuller description would not come amiss to such of your subscribers as may wish to try them.

The fresh root is cut into lengths, and can be bent at any desired curve, and thus dried. When thoroughly dry, the rough exterior is scraped off. The end is dipped about two inches into water, and heated over a lamp. A series of parallel longitudinal cuts is then made, nearly perpendicular to the bark, and through it to the wood beneath. The cuts are from one eighth to one twelfth of an inch apart and reach from the end of the stick about one inch to an inch and a half back. The end, so far as the cuts run back, is again dipped into water and heated. The strips of bark made by the cuts are lifted from the wood, care being taken not to

break them from their attachment at their base. They are again dipped and heated, when they can be bent back at right angles, to allow the end of the wood to be cut off nearly as far back as the bark is slit up. The end of the wood is trimmed to a conical shape. It is again dipped and heated, and with a strong twine the bark, now a hollow cylinder, is wound down firmly to the conical end of the wood, and beyond it into a solid cylindrical tip. When thoroughly dry, the tip is rounded and the whole surface of the root finished with sandpaper.

It is ready for use by soaking about five minutes in carbolized water.

If it be desirable to use the same dilator again, it is to be wiped immediately after using, and when dry finished again with sandpaper. This can be repeated so long as the tip remains. The smaller sizes can be bent when seasoned, by wetting and heating, but not so readily as when green. The roots are almost perfectly cylindrical, and are found of any size from two inches in diameter down. Dr. Skene has sufficiently attested their value as dilators. I find them very good as applicators of iodized phenol to the mucous membrane of the cervix and fundus uteri. When soaked for use, they are simply dipped in the medicament, and enough adheres to the mucilaginous surface. Such a sized bougie should be used as will thoroughly distend the cervical canal, thus applying the medicament to every part of the surface, while at the same time it is so smooth that it will produce the minimum of mechanical injury. For this latter reason I also use them instead of a metallic sound, for restoring a misplaced uterus to its normal position. Very truly yours,

L. B. TUCKERMAN.

AUSTINBURG, ASHTABULA COUNTY, OHIO. }
December 28, 1880.

CORRECTION.

MR. EDITOR,—I have just perused the editorial remarks in your journal of the 2d inst. on the death under ether at Cincinnati. I there find the extraordinary statement that in the debate on the subject "Dr. Reeve said, 'I never draw the patient's tongue out at all'" (as a means of resuscitation). No such words of mine can be found in the report of that debate. On the contrary, in detailing in that debate a case of chloroform accident seen and treated by me, it is distinctly stated that the tongue was pulled out simultaneously with lowering the patient's head. See *Cincinnati Lancet and Clinic*, October 30th, page 389.

This may appear a very small matter to trouble you about, but it certainly is not pleasant to be represented to the readers of a widely circulated journal as occupying upon a scientific subject a position directly opposite to the one held. There is the strongest evidence in favor of pulling out the tongue as a means of resuscitating patients under anæsthetics, and I have always appreciated it and always been prepared to put the measure in force. Very respectfully yours,

J. C. REEVE.

DAYTON, OHIO, December 24, 1880.

The remark as to drawing out the tongue should have been attributed to Dr. Young, whose remarks in the debate followed those of Dr. Reeve. The other remarks attributed to Dr. Reeve are, we believe, correctly quoted. — Ed.

Deaths reported 2494; 915 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping cough, erysipelas, and fevers) 550, consumption 573, lung diseases 355, diphtheria and croup 242, scarlet fever 108, small-pox 59, diarrhoeal diseases 35, typhoid fever 33, erysipelas 22, whooping-cough 17, malarial fevers 16, cerebro-spinal meningitis 10, measles eight. From *diarrhoeal diseases*, New York 17, Baltimore, New Orleans, and New Haven three, Brooklyn and Boston two, Cincinnati, District of Columbia, Pittsburgh, Lowell, and Worcester one. From *typhoid fever*, Cincinnati and Pittsburgh four, New York, Philadelphia, and Baltimore three, Boston, New Haven, Holyoke, and Taunton two, New Orleans, District of Columbia, Buffalo, Providence, Charleston, Worcester, Somerville, and Brockton one. From *erysipelas*, New York six, Philadelphia four, Cincinnati three, Brooklyn two, Baltimore, New Orleans, District of Columbia, New Haven, Worcester, Gloucester, and Brookline one. From *whooping-cough*, New York five, Philadelphia four, Baltimore three, Cincinnati two, Brooklyn, Providence, and Cambridge one. From *malarial fevers*, New York nine, Baltimore and New Orleans two, Brooklyn, District of Columbia and New Haven one. From *cerebro-spinal meningitis*, New York and New Orleans two, Philadelphia, Baltimore, Cincinnati, Milwaukee, Lynn, and New Bedford one. From *measles*, New York six, Milwaukee and Gloucester one.

One hundred and ten cases of diphtheria, 103 of scarlet fever, three of measles, and three of typhoid fever were reported in Brooklyn; small-pox one in Boston; scarlet fever 37, diphtheria 16, in Milwaukee; diphtheria five, in Somerville.

In 37 cities and towns of Massachusetts, with a population of

1,052,636 (population of the State 1,783,086), the total death-rate for the week was 21.21, against 20.86 and 21.32 for the previous two weeks.

For the week ending December 11th, in — German cities and towns, with an estimated population of 7,713,386, the death-rate was 22.9. Deaths reported 3410; 1558 under five; pulmonary consumption 462, acute diseases of the respiratory organs 285, diphtheria and croup 180, scarlet fever 106, whooping-cough 61, typhoid fever 57, measles and *rötheln* 56, puerperal fever 16, small-pox (Königs-berg) two, typhus fever (Po-en) one. The death-rates ranged from 10.1 in Potsdam to 31.9 in Cologne; Königsberg 28.1; Breslau 28.1; Munich 25.1; Dresden 21.2; Berlin 23.8; Leipzig 19; Hamburg 24.7; Hanover 21.4; Bremen 22.4; Cologne 31.9; Frankfurt 19.6; Strasburg 23.6.

For the week ending December 18th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 19.4. Deaths reported 2793; acute diseases of the respiratory organs 307, scarlet fever 129, whooping-cough 74, measles 63, small-pox (London 33) 34, fever 32, diarrhoea 24, diphtheria 19. The death-rates ranged from 13 in Wolverhampton to 26 in Nottingham; Sheffield 17, Leeds 18; London, Bristol and Birmingham 20; Manchester and Liverpool 21. In Edinburgh 21; Glasgow 19; Dublin 26.

In the 20 chief towns in Switzerland for the week ending December 18th, population 522,856, there were 21 deaths from acute diseases of the respiratory organs, diarrhoeal diseases eight, typhoid fever six, diphtheria and croup four, small-pox three, scarlet fever two, whooping-cough one.

The meteorological record for the week in Boston was as follows: —

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 1, 1881, TO JANUARY 7, 1881.

BAILY, E. I., lieutenant-colonel and surgeon. Granted leave of absence for two months. S. O. 277, A. G. O., December 30, 1880.

WHITE, C. B., major and surgeon. Relieved from the duty assigned him in S. O. 229, October 25, 1880, from A. G. O., and to report to the surgeon-general. S. O. 276, A. G. O., December 29, 1880.

WILLIAMS, J. W., major and surgeon. To report to the commanding officer, Department of Arkansas, for assignment to duty, temporarily, as medical director of that department. S. O. 2, A. G. O., January 5, 1881.

BROWN, J. M., captain and assistant surgeon. The leave of absence granted him in S. O. 264, December 2, 1880, Department of the Missouri, is extended three months. S. O. 2, C. S., A. G. O.

CARTER, W. F., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to leave the department. S. O. 265, Department of Texas, December 28, 1880.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, OCTOBER 1, 1880, TO DECEMBER 31, 1880.

BAILHACHE, P. H., surgeon. Detailed as chairman board of examiners of candidates for promotion. October 6, 1880. To proceed to Norfolk, Va., as inspector. November 1, 1880. Detailed as president board of inquiry to meet in St. Louis, Mo., November 17, 1880. November 9, 1880. Upon conclusion of duties under orders of November 9th, to proceed to Dubuque, Iowa, La Crosse and Milwaukee, Wis., Chicago, Ill., Detroit, Mich., and Buffalo, N. Y., as inspector. November 10, 1880.

MILLER, T. W., surgeon. Detailed as member board of inquiry to meet in St. Louis, Mo., November 17, 1880. November 9, 1880.

PERVIANICE, GEORGE, surgeon. Detailed as recorder board of inquiry to meet in St. Louis, Mo., November 17, 1880. November 9, 1880. Upon conclusion of duties under orders of November 9th, to proceed to Louisville, Ky., as inspector. November 19, 1880.

DOERING, E. J., surgeon. Granted leave of absence for thirteen days from January 3, 1881. December 29, 1880.

SMITH, HENRY, passed assistant surgeon. To proceed to Key West, Fla., and assume temporary charge of the service at that port. December 13, 1880.

FISHER, J. C., passed assistant surgeon. Detailed as recorder board of examiners of candidates for promotion. October 6, 1880.

KEYES, H. M., assistant surgeon. To report to president board of inquiry, November 17, 1880. November 10, 1880.

COOKE, H. P., assistant surgeon. To proceed to Galveston, Texas, and assume charge of the service at that port, relieving Assistant Surgeon Guiteras. December 14, 1880.

HEATH, W. H., assistant surgeon. Granted leave of absence for twenty days from October 21, 1880. October 20, 1880. To

proceed to Buffalo, N. Y., and assume temporary charge of the service at that port, relieving Assistant Surgeon Cooke. November 18, 1880. To assume charge of the service at Buffalo. December 14, 1880.

GUITERAS, JOHN, assistant surgeon. To proceed to Galveston, Texas, and assume temporary charge of the service at that port, relieving Passed Assistant Surgeon Smith. December 13, 1880. When relieved by Assistant Surgeon Cooke to rejoin his station. December 15, 1880.

WHEELER, W. A., assistant surgeon. To proceed to Pittsburgh, Pa., and report for temporary duty to Surgeon Purviance. November 10, 1880. Relieved from further duty at Pittsburgh, and ordered to report to Surgeon Fessenden at New York. November 27, 1880.

BENSON, J. A., assistant surgeon. To proceed to Boston, Mass., and report for temporary duty to Surgeon Vansant. October 15, 1880.

BANKS, C. E., assistant surgeon. To act as inspector of unserviceable hospital property at San Francisco, Cal. November 2, 1880.

RESIGNATION. BROWN, F. H., passed assistant surgeon. Resignation accepted by the secretary of the treasury, to take effect November 5, 1880. October 7, 1880.

PROMOTION. GOLDSBOROUGH, C. B., passed assistant surgeon. Promoted to be passed assistant surgeon from October 14, 1880. October 14, 1880.

DEATH. GLAZIER, W. C. W., assistant surgeon. Died at Key West, Fla., of yellow fever, December 12, 1880.

DISMISSED. KEYES, H. M., assistant surgeon. Dismissed the service, to take effect December 31, 1880. December 24, 1880.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held on Monday January 17, at eight o'clock, in the hall, 19 Boylston Place. Reader, Dr. Norton Folsom. Dr. Cushing will report a Case of Oily Urine, with Autopsy. A. T. CAROT, Secretary.

Lectures.

A CASE OF TRAUMATIC EPILEPSY.

PENNSYLVANIA HOSPITAL. SERVICE OF DR. R. J. LEVIST.

GENTLEMEN,—The study of that curious diseased condition known as epilepsy naturally divides itself into two grand divisions, namely, traumatic and idiopathic epilepsy; of course the phenomena presented in both conditions are nearly allied, still there are some points of difference. Before proceeding to consider the case of J. G., aged thirty-five, it may be well to tell you what is meant by the terms traumatic and idiopathic epilepsy. Traumatic epilepsy is a diseased condition of the nervous system due to violence to the cerebral structures, or to pressure exerted upon the cerebral hemispheres by reason of depressed portions of bone, the results of fractures of the skull, resting upon those structures. Idiopathic epilepsy, on the other hand, finds its origin in some diseased condition of the cerebral mass not dependent on extraneous causes, but on a degenerated condition of the cerebral matter itself; or, again, it may be due to syphilitic or other deposits. This variety of the disease, however, concerns the physician more than the surgeon, and so I leave it to my *confères* of the medical staff to discuss more exhaustively with you. As to the time, frequency, and method of seizure in cases of traumatic epilepsy I have a few words to say. As a rule, traumatic epilepsy does not make its appearance until some time after the receipt of an injury; thus, for instance, in the case of J. G., now before you, three years elapsed from the time of the receipt of his injury till epileptic symptoms first manifested themselves. In the mean time he had gone about his business, and had experienced no unpleasant symptoms and no inconvenience of any kind; true, in this case a rather long period elapsed between the injury and its deplorable consequences, but it only serves to prove the truth of what I have just told you. Now, as a differential point, I may say that if this was a case of idiopathic epilepsy the symptoms would have probably made themselves manifest early in life without a history of any exciting cause, as we have seen in this case. Further, in idiopathic epilepsy the attacks may happen at night after the patient has retired, whereas in traumatic epilepsy the seizure is liable to come at any period of the day, and to be precipitated by any excitement which tends to engorge the cerebral circulation and thereby increase the pressure of the cerebral mass against the impinging fragment of bone. An idiopathic epilepsy may also happen during the day, and under exciting circumstances, but I now merely lay down a general rule, from which of course there may be many departures. As to the frequency of the attacks, in idiopathic epilepsy the frequency of the attacks increases in a direct ratio with the time of the duration of the disease; in other words, the longer the time that the patient has been a victim to the disease the more often do the attacks occur. While this proposition is true of idiopathic epilepsy, it may also to some extent be said to apply to the traumatic variety of the disease. In the latter case, however, it seems that for long periods at a time the brain appears to accommodate itself to, or to tolerate the presence of, the foreign body (which the bony projection practically is) pressing upon or into its substance. Now, for instance, in the case before you, the patient, who has now

almost become an imbecile, tells us that the attacks of epilepsy when they first made their appearance followed each other at long intervals, but that gradually they increased in frequency, until now he presents every two hours a peculiar cataleptic condition, these attacks coming on suddenly, and differing from an ordinary epileptic condition in that during their continuance he may maintain the upright attitude, the countenance and body becoming fixed and rigid, the eyes set and staring, whilst the other senses are in abeyance. On recovering from one of these spells, which, however, during the last two days have been somewhat ameliorated by large doses of bromide of potassium, he is unaware of what has taken place around him. These cases of traumatic epilepsy differ also somewhat from the idiopathic variety in the method of attack. In an idiopathic epilepsy the patient is sometimes made acquainted with the approach of a convulsion by means of certain peculiar phenomena, which have received the name of the "aura epileptica." A peculiar numbness and tingling in the ends of the fingers and toes, which, rapidly proceeding up the limbs, seems, as it were, to explode in a convulsion, has been repeatedly spoken of by various observers. In the same way a feeling as though a ball were being pushed up from the abdomen into the throat has also been commented upon. In cases of traumatic epilepsy these symptoms are not so often noticed, and, in fact, are frequently wanting. At times, instead of the disease being due to the pressure of depressed portions of bone, it seems to take origin from the pressure of the thickened membranes that remain when the operation of trephining has been performed; or again a hard cicatrix pressing down on a thin plate of bone which borders the space left vacant by the removal of a disc of bone may be at the root of the trouble. The history of the man before you is that thirteen years ago he was struck on the head over the upper and posterior portion of the parietal bone with a brick. A compound comminuted fracture was the result, for the relief of which the trephine was employed by a gentleman of Williamsport, in this State. For three years afterwards he got along very comfortably, at the end of which time, however, he grew somewhat intemperate, and then first appeared the epileptic seizures; his condition progressively became worse, until now, as I have already told you, he has a cataleptic seizure every two hours, which may terminate in an epileptic convulsion, or which convulsion may only make its appearance every two, three, or four days. From being an intelligent man he has become almost idiotic; this being the history of nearly all epileptics. On examining this man's skull I find over the parietal bone decided evidence of depression in the integuments over the spot from which the comminuted fragments were originally removed. Running backwards and upwards there is a hard, cicatricial ridge or elevation marking one of the lines of the depression. It is my impression that this is the point at which an injurious compression of the brain substance is being exerted, and not at the point where the section of bone was removed in the trephining operation. Acting on this supposition, I propose, this morning, to apply the trephine in the line of this cicatrix, hoping thus, and by elevating any other depressed portion of bone that can be found, to afford the man some relief, and to thus enable him to continue his business, which he is now unable to pursue. In the performance of the operation I shall use

a trephine whose cylinder is straight; in the hands of a novice or an awkward operator the conical trephine is better, there being less risk of perforating too deeply in its employment, owing to its somewhat tapering end. Upon making a trap-door incision through the scalp, — although many operators prefer a crucial incision in performing this operation, — I find a rather prominent, rounded edge of bone bounding the original opening. Having scraped off the pericranium, and being careful not to injure the dense membrane, which at this point protects the brain, I proceed to employ my trephine to remove this prominent edge. The instrument, being held in place by a movable pin till a groove has been cut into the bone, is given what might be styled a fore and back circular or rotary movement, the pin of the instrument being pushed up into its sheath after the trephine has made for itself a resting groove. A tooth-pick or ordinary quill is employed to determine the depth to which the instrument has penetrated, and the portion of the bone can readily be lifted out of its bed by means of an elevator, this latter instrument having been passed beneath the edges of the opening in order to discover if any depressed portion of bone remains. The operation may now be said to be terminated, and the scalp wound is brought together and a carbolyzed dressing employed.

A YEAR'S WORK IN OVARIOTOMY.¹

BEING TWENTY-FIVE SUCCESSIVE CASES OPERATED UPON BETWEEN NOVEMBER 26, 1879, AND NOVEMBER 28, 1880.

BY JOHN HOMANS, M.D.

I PROPOSE to describe very briefly these cases, and make a few comments upon any points of clinical interest that I have observed.

DOUBLE OVARIOTOMY; DERMOID CYST OF RIGHT OVARY AND COMMENCING CYSTIC DEGENERATION OF LEFT OVARY; RECOVERY.

CASE XIX.² Anne S., aged twenty-four, was admitted to Carney Hospital November 19, 1879. The tumor had been discovered three months before, and had grown rapidly. The girth at the umbilical level was thirty-two inches. Her general health was good.

Antiseptic ovariectomy was performed on November 26th. The pedicle of the right ovary was tied in halves with carbolyzed silk after compression by Dawson's clamp, and that of the left was tied in the same manner without the use of the clamp. In the wall of the cyst were found pieces of skin with hair growing on them, a plate of bone about two inches square, and a sebaceous cyst. Microscopical examination by Dr. A. T. Cabot showed that the flat piece of bone was true bone. Recovery was rapid. Miss S. writes me on July 25, 1880: "I have been unwell five times in eight months; three times within the last three months just as regular as I ever was. At those times I suffer more pain than I ever did before I was operated on." This fact has an important bearing on the usefulness of "Battey's operation." Both ovaries were, I think, thoroughly removed.

¹ Read before the Boston Society for Medical Improvement.

² The numbers refer to the author's whole series.

MULTILOCULAR CYST OF LEFT OVARY; RECOVERY.

CASE XX. Anna H., aged thirty-three, was operated upon December 21, 1879. Her general health had already begun to fail. The tumor had been discovered eight months before. Adhesions, broad and vascular, to the omentum and intestine were tied with silk or catgut, and then divided with Paquelin's thermocautery.

MULTILOCULAR CYST OF RIGHT OVARY; RECOVERY.

CASE XXI. Anne M. P., aged thirty-nine, was operated upon in her home in Boston on February 8, 1880. Her health was failing; she was confined to her bed, and had considerable oedema of her lower extremities. The tumor had been discovered five months before. There were no adhesions. Recovery was rapid.

CYST OF THE LEFT BROAD LIGAMENT; RECOVERY.

CASE XXII. The cyst was removed at the Carney Hospital on March 7, 1880. The umbilical girth was forty-three inches. The tumor had been known to exist for at least four years. Both ovaries were healthy. The fluid removed weighed twenty-six pounds and the cyst eleven ounces. Dr. A. T. Cabot reported that the fluid was slightly alkaline, sp. gr. 1.005, and that it contained a small quantity of albumen and no mucin. She recovered quickly.

MULTILOCULAR CYST OF THE LEFT OVARY; RECOVERY.

CASE XXIII. Laura A. M., aged fifty-seven, was operated upon in her home at Taunton, Mass., on March 23, 1880. The tumor was discovered about six months before. The cyst was much degenerated, more or less rotten, and friable. The pedicle was secured as usual. Recovery was rapid.

CASE XXIV. Anne L. S., aged eighteen, was operated upon at Carney Hospital April 1, 1880. The tumor weighed forty-five pounds. The adhesions were universal and intimate to the anterior parietes, and were burnt off with Paquelin's cautery. The pedicle was secured first by Dawson's clamp, then it was perforated by a double ligature of carbolyzed silk, and tied in halves, and finally was divided by Paquelin's cautery; Dawson's clamp was then removed, and the stump allowed to fall back into the pelvis. This method of treating the pedicle I have followed ever since. Recovery was rapid; but the patient was somewhat annoyed by an abscess in the wound discharging through the tracts of the sutures. Possibly this suppuration was caused by the cautery, which was used freely near the wound.

UNILOCULAR CYST OF LEFT OVARY; RECOVERY.

CASE XXV. Mrs. C., aged forty-eight, was operated upon at her home in Fall River, Mass., April 17, 1880. There were no adhesions. The pedicle was secured as in the last case. Recovery was very rapid.

CASE XXVI. Hannah T., aged fifty-eight, was operated upon at Carney Hospital on April 29, 1880. There were no adhesions; the pedicle was secured as usual. Recovery was almost immediate, the temperature never rising above 99° F. nor the pulse above 97 beats per minute.

MULTILOCULAR CYST OF LEFT OVARY; RECOVERY.

CASE XXVII. Fannie O. D., aged thirty-eight, was operated upon in her home at Mt. Holly, Vt., on May 18, 1880. There were no adhesions. The pedicle was secured as usual. Recovery was rapid.

UNILOCULAR CYST OF LEFT OVARY; RECOVERY.

CASE XXVIII. T. W. N., aged fifty-seven, was operated upon in her home in Boston on July 10, 1880. The tumor weighed forty-eight pounds. There were no adhesions. Recovery was very rapid. The temperature never rose above 99.5° F., nor the pulse above 85 beats per minute.

CYST OF THE LEFT BROAD LIGAMENT; RECOVERY.

CASE XXIX. S. F. E., aged forty-seven, was operated upon at the Carney Hospital on July 15, 1880. There were no adhesions. The fluid, which was limpid and clear, weighed eighteen pounds, and the delicate unilocular cyst a few ounces. Recovery was rapid.

MULTILOCULAR CYST OF RIGHT OVARY; RECOVERY.

CASE XXX. Abbe B., aged forty-seven, was seen in her home July 26, 1880. She was unable to leave her bed, and was evidently suffering from peritonitis and a low form of inflammation within the peritoneal cavity. Her case was not a promising one, as she was a stout, flabby woman, who had worked hard until she had to give up. She was removed to the Carney Hospital, and ovariectomy was performed on July 31st. The adhesions were recent and intimate between every portion of the cyst and the omentum and intestines. The omentum was half an inch thick, of a purple color, and showed itself when the peritoneum was opened. On separating the omentum from the cyst, and turning the former upwards upon the exterior of the abdomen, the cyst was seen. It was of a darkish-brown color, and beginning to be gangrenous, degenerating and inflamed inside and out. The cystic fluid was brown and commencing to decompose. More or less reddish ascitic fluid ran out. Some of the adhesions were separated with the fingers and some with Paquelin's cautery. The pedicle, which was very short, was compressed, tied, and burnt off at about the distance of a line from the intestine with which it was intimately incorporated. The temperature was 100.9° F. on the morning of the operation, and on the third day—that is, at the end of forty-eight hours—it had sunk to the normal level 98.5° F., and the pulse had fallen from 115 to 100. Recovery was rapid, and she went home at the end of two weeks. It may be asked, Why did this woman recover? Because her system was relieved of an exceedingly large mass undergoing decomposition and beginning to poison her blood, and the whole peritoneal cavity was washed clean. I should have said that the intestinal walls were velvety-looking and stiff like the right ventricle of the heart. The omentum was turned up and laid on a carbolized towel, and the intestines turned downwards on the pubes during the removal of the cyst. The cyst weighed two pounds, and the fluid eight and a half. The abdominal enlargement dated back about two years.

MULTILOCULAR CYST OF THE LEFT OVARY; RECOVERY.

CASE XXXI. Emma H., aged thirty, was operated on at the Carney Hospital on August 1, 1880.

There were no adhesions. The tumor weighed twenty-five pounds. Recovery was rapid.

CASE XXXII. Sarah J. S., aged twenty-nine, was operated on at the Carney Hospital on August 21, 1880. The adhesions were recent and easily broken down. The walls of the cyst were made up of a sarcomatous-looking material, in many places half an inch thick. Dr. A. T. Cabot reported that the sarcomatous-looking appearances were villous growths, the tops of the villi growing together and inclosing little cavities, from the walls of which new villi grew. The tumor belongs to the class called villous or papillomatous. The tumor weighed twenty-three pounds. Of these papillomatous tumors and their subsequent history I have spoken at a former meeting of the society.¹

MULTILOCULAR CYST OF LEFT OVARY; ASPIRATION OF CHEST; RECOVERY.

CASE XXXIII. Kate L., aged twenty-nine, was operated upon August 22, 1880, at the Carney Hospital. The tumor had been discovered about three months before. She had been tapped in May, and about three quarts of fluid drawn off. Her pulse was 104; her breathing was rather labored, and her left lower extremity was edematous. Her umbilical girth was forty-three inches. The cyst and its contents weighed fifty pounds; inasmuch as the material was semi-solid, and would not flow through a trocar, the cyst was necessarily removed piecemeal. At the conclusion of the operation the patient was very feeble, and her recovery seemed quite doubtful. The pulse ranged from 130 to 140, and the temperature stood at 100° F., and gradually rose to 101° F. on the third day. On the morning of the fourth day a severe and distressing attack of dyspnoea came on, lasting several hours. On examination the whole of the left thoracic cavity was found to be perfectly flat, and filled with fluid. By the advice and with the assistance of Dr. D. H. Hayden forty ounces of serum were drawn out by aspiration. The patient became somewhat livid, and coughed considerably, but this gradually passed off, and improvement and absorption went on rapidly, until, on the seventh day, the temperature had fallen to the normal standard and the pulse to 110. After this convalescence was rapid, and she went home on the twenty-eighth day after ovariectomy. I have never known of a case of aspiration of the chest after ovariectomy. Had I known of the presence of this fluid in the thorax before the operation I am sure that I cannot tell what plans I should have made. I attributed the rapid respiration to the pressure of the tumor against the diaphragm and the probably edematous condition of the lungs. The case was a very doubtful one, and one that I hesitated about and operated upon somewhat reluctantly, but the issue was successful, and perhaps aspiration after the operation was better surgery than aspiration before.

MULTILOCULAR CYST OF THE RIGHT OVARY; DEATH.

CASE XXXIV. Caroline F., aged forty-six, was operated upon at her home in Woburn, September 1, 1880. The patient's abdomen, buttocks, thighs, and legs were greatly swollen, her abdominal parietes were several inches thick from edematous swelling, and from the skin of the abdomen and the legs exuded serum, which ran from the bursting and eczematous cuticle. The patient was informed that I could give

¹ Vide Boston Medical and Surgical Journal, January 22, 1880

her no encouragement that the tumor could be removed, but as its contents would not flow through a trocar, and as her death was certain within a few weeks, an exploratory incision seemed a sensible thing to do. She decided to have this done. On opening the abdomen the tumor was found to be practically solid. An opening was made in the tumor with the cautery, and its size reduced as rapidly as possible; the adhesions were broken down, and the tumor removed. The relief to the patient was immense, and for forty-eight hours it seemed as if she would certainly recover; but the weather became excessively hot and sultry, and death took place from exhaustion on the fifth day. The tumor weighed thirty-nine pounds.

MULTILOCULAR CYST OF THE LEFT OVARY; RECOVERY.

CASE XXXV. Margaret K., aged forty-seven, was operated upon at Auburndale on September 2, 1880. The tumor weighed forty pounds. There were no adhesions. The wall of the cyst was as delicate as the membrane of the chorion, and when the peritoneum was divided a semi-solid material resembling calf's-foot jelly or vaseline burst through and flowed out. This was scooped out and squeezed out, and more or less was entangled in sponges and brought out. The pedicle, which was very delicate and friable, was secured in the usual manner. Recovery was interrupted, and was due to the antiseptic precautions and to prolonged and patient sponging and wiping of the peritoneal cavity.

MULTILOCULAR CYST OF THE LEFT OVARY; DEATH.

CASE XXXVI. Lucy A., aged twenty-seven, was operated upon at the Carney Hospital on September 7, 1880. The diagnosis was a cyst of the left ovary, with more or less pelvic adhesions. The tumor was found to be intimately adherent to the intestines, uterus, and pelvic organs; its nourishment was mainly derived from the mesentery. It was almost impossible to tell where the outline of the bowel ended and that of the cyst began, and after patient efforts and considerable hemorrhage all attempts to separate the outer covering of the cyst were abandoned, and it was enucleated, leaving its outer envelope attached to the intestine and uterus. The patient never rallied from the shock of the operation, and died in about fourteen hours. In structure the tumor was papillomatous.

MULTILOCULAR CYST OF LEFT OVARY; RECOVERY.

CASE XXXVII. Louisa F., aged thirty-three, was first seen at the Carney Hospital on September 9, 1880. On August 31st she had been tapped at her home in West Scituate by Dr. French, and thirty-five pounds of fluid had been removed. On September 9th I tapped and removed thirty pounds of fluid, partly ovarian and partly ascitic. On the 23d all oedema of the legs and abdomen had subsided, and the cyst was removed. The adhesions were recent and slight. The tumor and its contents weighed sixteen pounds. Recovery was rapid.

CASE XXXVIII. Sarah S., aged forty-eight, was operated upon October 2, 1880. Her case showed the advantages of preliminary tapping in certain cases, of which the previous one and this one are good instances. Ten days before the operation her lower extremities and abdominal parietes were excessively oedematous, and she was tapped, so that by the time of

the operation the oedema had greatly subsided and her condition was very good. The adhesions were new and old, and almost universal to the parietes. The tumor was largely solid. Recovery was uninterrupted.

MULTILOCULAR CYST OF THE RIGHT OVARY; RECOVERY.

CASE XXXIX. Rosa Z., aged thirty-eight, was first seen on June 15, 1880. As she was a Cuban, and could neither speak nor understand English, I was unable to convince her that removal of the cyst would be better than tapping, and as she had been told that the cyst might not fill up after tapping I consented to tap her, and removed thirty-seven pounds of chocolate-colored ovarian fluid. On October 6th ovariectomy was done at the Carney Hospital. The operation, I thought, would be a simple one, but solid and old adhesions united the cyst to the omentum and to the uterus and pelvis. The uterus was almost as much a part of the tumor as the interior cysts, and projected into the cyst wall so that its outline could be felt from the interior of the cyst. The outer membrane of the cyst was left upon the uterus and pelvis, and the cyst more or less enucleated. The pedicle was secured in several parts wherever there seemed to be a likelihood of hemorrhage. Recovery was very rapid.

UNILOCULAR CYST OF THE LEFT OVARY; RECOVERY.

CASE XL. Sarah M., aged forty-five, was operated upon at the Carney Hospital on October 24, 1880. The tumor had been discovered six months before, and had apparently been burst in April by the patient's lying on her stomach. About three weeks after the discovery of the tumor Mrs. M., feeling uncomfortable, tried the experiment of turning over and lying on her stomach. Immediately she felt something give way, and could no longer find the tumor. Vomiting came on, and she had great pain for twenty-four hours. No adhesions were set up, however. Recovery was sufficiently rapid, and she left the hospital on the twenty-first day.

In this case and in the one which followed there occurred a slight attack of phlegmasia dolens. On the twelfth day after ovariectomy the patient was feeling so well that she begged to sit up for a few minutes. She was allowed to do so, and walked a few steps to a sofa. On the next day she complained of pain in her hip and leg, and in a day or two the right leg measured about an inch more in circumference than the left. The temperature rose to 101.6° F., and did not sink to the normal height for a week. Now, January 5, 1881, although the patient has gained flesh and is feeling well, the right leg is somewhat larger than the left. The ovary that was removed was on the left side. There is still some swelling of the leg at the close of the day.

MULTILOCULAR DERMOID CYST OF THE LEFT OVARY; RECOVERY.

CASE XLI. Mrs. S., aged thirty-one, was operated upon at the Carney Hospital on November 6, 1880. The presence of the tumor had been known for at least four years. The tumor weighed twenty-two pounds, and contained in one spot a mass of hair, epithelium, and bone or cartilage. Recovery was rapid, but was attended with the same swelling of the lower extremity as in Case XL. There has also been a slight feeling

of soreness on deep pressure in the left iliac region. Mrs. S. was very anxious to leave the hospital, and seeming perfectly well she was allowed to ride home in a comfortable carriage on the nineteenth day after ovariectomy. Her ride tired her very much, and caused severe pain throughout the abdomen for about two hours after reaching home. Soon the same sort of indolent swelling as in the last case took place, and now, January 1, 1881, still exists slightly; but the tenderness in the groin has entirely subsided, and the patient is gaining flesh, and looks and feels perfectly well.

MULTILOCULAR CYST OF THE RIGHT OVARY; RECOVERY.

CASE XLII. C. W., aged thirty-one, was operated upon at the Carney Hospital on November 18, 1880. I had seen her at my office some weeks previously, and had thought her tumor probably uterine, with more or less ascites. She was much distressed in her mind and was quite worn and feeble. Her appetite was poor, she did not sleep well, her breathing was short, and she had coughed much for three weeks. Her pulse was rapid and feeble. My diagnosis was ascites, with a tumor more or less cystic and either uterine or ovarian; more probably the former, because the uterus and tumor were so intimately connected that the least motion communicated to the latter was transmitted at once to the former. On lifting the tumor the uterus was pulled upwards, on moving the tumor to one side the uterus was moved also, as if it were a part of the tumor. Finally, I said, "Whenever you feel that your life is a burden to you on account of this tumor, let me know, and I will try to remove it and cure you." It was not many weeks before she came and asked to have the operation attempted. The result showed that my diagnosis was wrong and that the tumor was ovarian. At the operation a portion of the cyst was found to be intimately adherent to the small intestine; this portion, about an inch and a half long and half an inch wide, was cut out and left on the intestine. In the pelvis there were practically two pedicles: one, the ordinary pedicle, comprised of the broad ligament and Fallopian tube, belonging to the right ovary, was secured as usual; the other consisted of a series of bands, in appearance resembling the cicatrized contracted bands of burns, such as one sees between the chin and sternum, for instance. These bands, altogether about two inches broad, connected the uterus and the ovarian cyst intimately, and this connection it was which had conveyed the impression that the tumor was a growth from the uterus. I secured these adhesions in an *écraseur*, and divided them with Paquelin's cautery. The patient went on very well until the twelfth day, when she had nose-bleed, and on the next day a hæmorrhage that seemed to me to come from the lungs. She went home perfectly well on the twenty-seventh day after ovariectomy.

CASE XLIII. C. A., aged fifty-two, was operated upon at the Carney Hospital on November 28, 1880. A fortnight before she had entered the hospital, but in such a state of alcoholism that the operation was deferred until her condition became more natural. The pedicle was extremely thick and several inches broad, so much so that it was difficult to include it in a Dawson's clamp, and when burned off and tied presented a stump as thick as my wrist. The only adhesion was a broad and intimate one to the uterus. The tumor weighed twenty-nine pounds. Her recovery was very satisfactory; her temperature never being above 99°

F., except on the evenings of the second and third days, when it stood at 100.8 F. and 100 F. respectively.

These cases, so far as they go, are a proof of the great value of the antiseptic method, or Listerism. I like this latter name because it is concise and identifies Lister's name with the magnificent principle which he has discovered and the method which he has introduced. The number of cases is small, but I am very sure that the percentage of recoveries is much higher than it would have been without Listerism, and the ratio is about what may be expected in cases done antiseptically by an experienced operator. So much has been written and said about the diagnosis of ovarian tumors and the method of performing ovariectomy that any remarks on these subjects would be out of place and superfluous. Any one wishing to know what can be accomplished by experienced operators, practicing perfect attention to all the details of cleanliness, without the spray, is referred to the writings of Mr. Wells and Dr. Keith.¹

A MORAL DUTY OF THE OVIOTOMIST.

I think there is a moral duty involved in undertaking to practice ovariectomy, namely, that a surgeon is bound at times to operate in cases where he can give but little hope for a favorable result. This becomes more and more a duty as time goes on and the operation becomes more and more firmly established. In the earlier efforts to make the operation one to be advised and urged, it would have been wise to select for operation only those cases almost certain to recover, in order that ovariectomy might not fall into disrepute, but now I think an ovariectomist ought to be willing to operate in a case like Number XXXIV., for instance, where the contents of the tumor were so thick that they could only be removed through an incision which would admit the hand. Here there was a possibility of recovery and a certainty of a speedy and distressing death. Much precious time had been lost in this case on account of the supposed existence of pregnancy, but after a lapse of a year without parturition it was found that the tumor was ovarian. In this case, if the fluid had been limpid, the patient ought to have been tapped, and probably when her *œdema* and general dropsy had subsided ovariectomy would have been successful.

THE PERSISTENCE OF MENSTRUATION AFTER DOUBLE OVIOTOMY.

This is illustrated in Case XIX. Miss S. states in a letter lately received: "To-day [November 26th] is the anniversary of my operation. I have gained seventeen pounds in the year, and have been unwell *regularly* for the last eight months. I suffer very much pain at those periods." In a previous letter she writes that her menstrual periods have been very painful since the removal of the ovaries. — much more so than before. Now it is possible that there may be a third ovary, or that some of the ovarian substance containing ova may have been left; but neither of these conditions is probable, and a ligatured stump of an ovary is not at all likely to be able to discharge ova through its tied and cicatrized surface. So far as this case goes it would not encourage one to perform Battley's operation in order to bring about the menopause.

¹ Dr. Keith's article on Ovariectomy before and since the Introduction of Anti-septics, in the British Medical Journal for October 19, 1878, will well repay perusal.

PAIN AFTER OVARIOTOMY.

In regard to pain after ovariectomy patients vary very much: some have very severe pain at a single point in the small of the back, and some complain only of a slight feeling of soreness. Almost every patient requires an opiate, at least once. Some are much distended with wind and suffer in consequence, while in others the intestines remain collapsed, and we find the same deep hole, filled with wrinkled and superfluous skin, when we remove the stitches a week after the operation, that was left when the wound was sewed up; so remarkable is this sometimes that the integument has to be unrolled and unfolded to find the line of incision. This presence or absence of pain, or distention or flatness, seems to have no relation to the amount of handling the peritonæum has undergone.

FLOWING AFTER OVARIOTOMY.

A moderate amount of hæmorrhage from the uterus is not very unfrequent after ovariectomy, and is, as far as I know, of no especial importance.

TEMPERATURE AFTER OVARIOTOMY.

The bodily temperature after this operation and during convalescence is generally low. I mean lower than one would naturally expect; it often does not rise to 100° F., and seldom reaches 101° F.¹

PRELIMINARY TAPPING.

Tapping before ovariectomy, except for purposes of diagnosis or to remove œdema, is an evil, because it sometimes gives rise to adhesions, or causes more or less suffering and pain.

The lady whose case is described in No. XXVII. writes to me: "Advise your patients never to be tapped. I suffered more after tapping than I did after the operation." Mr. Wells has shown, however, that ovariectomy in a large number of cases is as successful in those who have been tapped as in those who have not. The emptying of a cyst by the slow process of aspiration is a most pernicious practice and quite harmful, while simple tapping with a good-sized trocar is almost in comparison innocuous. The attempt to completely empty a cyst in this way seems (at least in my experience) to be followed by a complete degeneration and softening of the contents of the sac and a deposit of a layer of friable lymph on its inner wall. This condition of things can generally be inferred from the pain and constitutional irritation that the patient suffers. Tapping before ovariectomy is always necessary in such cases as XXXVII. and XXXVIII., where there is great œdema of the abdominal walls and lower extremities. If, after the tapping, the patient's general condition markedly improves and the œdema subsides, you may hope for the best results from ovariectomy.

ASPIRATION OF THE CHEST FOR PLEURITIC EFFUSION AFTER OVARIOTOMY.

Case XXXIII. is unique, so far as I know, in regard to the tapping of the chest for pleuritic effusion on the fourth day after ovariectomy. I cannot say whether there was fluid in the chest before the operation, but had I known that there was I should have inferred that it was a part of the general dropsy, and that it would be absorbed rapidly after the removal of the tumor,

just as œdema of the legs generally disappears entirely within four days after ovariectomy.

PHLEGMASIA DOLENS AFTER OVARIOTOMY.

Cases XI. and XII. illustrate the rare occurrence of a mild form of phlegmasia dolens after ovariectomy. When this occurs the extremity on the opposite side to that from which the ovary was removed seems more likely to be affected than the one on which the pedicle has been tied; or, to speak more carefully, it has been found in four cases in which this complication has occurred that three were on the opposite side to the pedicle and one on the same side. In the *American Journal of the Medical Sciences* for July, 1880, Dr. Walter F. Atlee, of Philadelphia, relates a case of ovariectomy in which phlegmasia dolens followed the operation. Dr. Atlee remarks, "This complication of the operation for the removal of an ovarian cyst I had never before seen or heard of." He quotes a like case reported by Dr. Galabin, of Guy's Hospital, in the *British Medical Journal* of March 13th. Both of my cases were very mild, though tedious. The cause of this inflammation of the vein is not at all apparent. Dr. Galabin has no theory to offer, and Dr. Atlee is inclined to think that the cause was septic. In my cases walking about seems to have lighted up the trouble, but exactly why it should in these cases and not in others I am unable to explain.

HEMOPTYSIS AFTER OVARIOTOMY.

I do not remember to have read any account of the occurrence of hæmorrhage from the nose and lungs after ovariectomy, such as occurred in Case XLII. Whether this hæmorrhage was salutary and was similar to the hæmorrhages from the uterus, which I have mentioned above, or whether it was accidental and entirely unconnected with the operation and the precursor of phthisis, I cannot decide, but the future career of the patient will be interesting to follow.

TIME OF LEAVING HOSPITAL AFTER OPERATION.

Patients generally are ready to leave the hospital at the end of the third week after the operation; some leave sooner and some remain later. I think that most of the favorable cases are able to go home at the end of three weeks.

There are certain details of the operation and general rules that may be worth mentioning. Always clean up as thoroughly as you can a dirty, inflamed peritoneal cavity. I always do this, and have several times wiped masses of lymph off from the intestines and peritonæum; perhaps this latter action is unnecessary, but the patients have recovered, and I have not regretted doing it. I generally cut out and leave behind any portion of the cyst intimately adherent to a coil of intestine; it is better to do this than to run the risk of rupturing the bowel or causing hæmorrhage from its surface, which it is not easy to control. I have always followed Mr. Spencer Wells's advice not to yield to the temptation to remove a fibroid from the uterus during an ovariectomy; the desire to do so is very strong, but I think the safer way is to leave them alone, and, although I have one or twice seen them well pediculated, I have not meddled with them. I always compress the pedicle with Dawson's clamp (a very simple and powerful instrument which has done me good service), then burn off the pedicle with Paquin's cautery, tie with a double ligature (*in the sul-*

¹ In the *British Medical Journal* for December 18, 1880, will be found an interesting discussion on hyperpyrexia after Listerian ovariectomy at the Royal Medical and Chirurgical Society.

cus made by the clamp), remove the clamp, and drop the stump. I do this because two of the most successful operators, Drs. Keith and Bradford, use one the cautery and the other the ligature, and so I use both. I dare say that either would be sufficient, but I see no objection to my method, and am satisfied with it. I never use catgut for tying the pedicle, but always carbolized silk. I lost a case from hemorrhage after tying with catgut, and have never used it since. So far as my experience has gone, abdominal hernia rarely occurs after ovariectomy unless the patient is very careless. Mr. Wells advises that the abdomen be supported by adhesive plaster for six weeks after the operation,

and that a proper abdominal belt be worn for at least a year. In the only cases I have known the patients were ignorant and careless, and took off all support, and worked hard within a few weeks after recovery.¹ I continue to find my operating table, which I have shown at one of the society's meetings, very convenient. I can turn a patient nearly over without having the least anxiety as to her slipping off the table, while the board is securely held at any angle by the ratchet or pull in the cogwheel. I have declined to operate but in a single case during the last year, — a case of malignant disease with marked cachexia. This case was operated upon by another physician, but the result was fatal.

CASES OF OVIARTOTOMY FROM NOVEMBER 26, 1879, TO NOVEMBER 23, 1880.

No.	Date.	Place of Operation.	Condition.	Age.	Length of Incision.	Adhesions.	Treatment of Pedicle.	Weight of Tumor.	Result.	Remarks.
1	Nov. 26, 1879.	Carney Hospital.	S.	24	6 in.	Slight.	Tied with carbolized silk and dropped back.	12 lbs.	Recovery.	Both ovaries removed. Menstruation regular, but more painful than before ovariectomy. One cyst dermoid.
2	Dec. 21, 1878.	Do.	S.	33	4 in.	Omental and intestinal.	Do.	25 lbs.	Recovery.	
3	Feb. 8, 1880.	Boston.	M.	39	4 in.	None.	Do.	25 lbs.	Recovery.	
4	March 7, 1880.	Carney Hospital.	M.	28	3 in.	None.	Do.	27 lbs.	Recovery.	Cyst of the left broad ligament.
5	March 23, 1880.	Taunton.	M.	37	3½ in.	Slight.	Do.	20 lbs.	Recovery.	
6	April 1, 1880.	Carney Hospital.	S.	18	5 in.	Universal and intimate to anterior parietes, and slight to omentum.	Tied as above, and burnt off with Paquelin's cautery.	45 lbs.	Recovery.	Adhesions burnt off with Paquelin's cautery.
7	April 17, 1880.	Fall River.	M.	48	3 in.	None.	Do.	83 lbs.	Recovery.	
8	April 29, 1880.	Carney Hospital.	S.	58	2½ in.	None.	Do.	14 lbs.	Recovery.	
9	May 18, 1880.	Mt. Holly, Vt.	M.	38	3½ in.	None.	Do.	50 lbs.	Recovery.	
10	July 10, 1880.	Boston.	M.	57	4 in.	None.	Do.	48 lbs.	Recovery.	
11	July 15, 1880.	Carney Hospital.	S.	47	4 in.	None.	Do.	18 lbs.	Recovery.	Cyst of left broad ligament.
12	July 31, 1880.	Do.	M.	47	6 in.	Intimate, and recent to omentum and intestines.	Do.	11 lbs.	Recovery.	The omentum was turned up and laid on a carbolized towel, and the intestines turned downwards towards the pubes during the removal of the cyst.
13	Aug. 1, 1880.	Do.	M.	30	3½ in.	None.	Do.	25 lbs.	Recovery.	Dermoid cyst.
14	Aug. 21, 1880.	Do.	M.	29	6 in.	Almost universal and recent to parietal peritoneum.	Do.	23 lbs.	Recovery.	Papilloma.
15	Aug. 22, 1880.	Do.	M.	20	6 in.	Slight.	Do.	51 lbs.	Recovery.	Forty ounces of serum removed by aspiration from the left thoracic cavity on the fourth day after ovariectomy.
16	Sept. 1, 1880.	Woburn, Mass.	M.	46	8 in.	To peritoneum, small intestine, and diaphragm; firm and old.	Do.	39 lbs.	Death.	Exhaustion on fifth day. Very hot weather.
17	Sept. 2, 1880.	Auburndale.	M.	47	7 in.	None.	Do.	40 lbs.	Recovery.	Fluid gelatinous.
18	Sept. 7, 1880.	Carney Hospital.	M.	27	6 in.	Intimate and old, or congenital, to small intestine, mesentery, and uterus; in fact, incorporated with them.	Do.	20 lbs.	Death.	Shock. Papilloma.
19	Sept. 23, 1880.	Do.	M.	33	4 in.	Recent to anterior peritoneum.	Do.	16 lbs.	Recovery.	Sixty-five pounds of ascitic and ovarian fluid removed by tapping within the last three weeks preceding the operation.
20	Oct. 2, 1880.	Do.	S.	48	5 in.	Universal, old and new, to peritoneum.	Do.	38 lbs.		
21	Oct. 6, 1880.	Do.	W.	38	3½ in.	Solid, old, to uterus, oment., and pelv.	Do.	15½ lbs.	Recovery.	Cyst more or less calcified.
22	Oct. 23, 1880.	Do.	M.	45	2½ in.	None.	Do.	10½ lbs.	Recovery.	
23	Nov. 6, 1880.	Do.	W.	31	2½ in.	None.	Do.	21½ lbs.	Recovery.	
24	Nov. 15, 1880.	Do.	S.	31	6 in.	To intestine and uterus.	Do.	18 lbs.	Recovery.	The portion of the cyst adherent to the bowel was cut out and left behind.
25	Nov. 28, 1880.	Do.	W.	52	3 in.	Do.	Do.	30 lbs.	Recovery.	

— A London chemist was suspected of selling drugs for the purpose of procuring abortions, and a policeman undertook to procure evidence against him. For this purpose he called, in citizen's dress, upon the chemist, and represented that a friend of his was in difficulty, and he wanted something to aid her. The druggist wanted to see the woman, and accordingly a

female attaché of the force accompanied the policeman, and the desired material was procured. The grand jury found a true bill against the chemist, and also a bill against the police for conspiracy. The result is not yet determined.

EUROPEAN AND AMERICAN ANATOMY ACTS
COMPARED.¹

BY EDWARD MUSSEY HARTWELL, M. A.,
Fellow of the Johns Hopkins University.

THE guild spirit which led to the incorporation of the Edinburgh surgeons as a "company," in 1505, and the incorporation of the "Mystery and Commonalty of Barbers and Surgeons of London," in 1510, may be said to characterize the majority of our American medical colleges which are, as has been well said by President Eliot, managed as commercial ventures. This trading, monopolizing spirit is more marked in British than in Continental schools of medicine. The radical difference between European and American medical education results from the woful lack on this side of the Atlantic of the well-considered, consistent, and responsible state supervision exercised over the teachers, students, and practitioners of medicine in most European countries. In no department of medical education is this difference more strongly emphasized than in that of anatomy. It is equally clear whether we consider the training and attainments of the teachers, the amount of practical knowledge required of the students, or the laws regulating the supply of material in this department.

Such apathy regarding anatomical studies as characterized the legislators of Indiana and Ohio prior to the desecration of the Harrison tomb, in 1878, must not be considered distinctively American. The English anatomists were denied adequate protection until the discovery, in 1828, that some fifteen murders had been committed by Burke and Hare, in Edinburgh, for the single purpose of selling the bodies of their victims. This discovery aroused Parliament to pass the Warburton Anatomy Bill, which became a law August 1, 1832. The preamble of this act sets forth the indispensable nature of anatomical examinations; the insufficiency of the legal supply of human bodies for such purposes; the fact that to meet the demand for subjects "divers great and grievous crimes have been committed, and lately murder;" and the expediency of giving "protection, under certain regulations, to the study and practice of anatomy." By the terms of this act, which is known as 2 and 3 Will. IV. chap. 75, the secretary of state for the home department in the United Kingdom and the chief secretary for Ireland are empowered to issue licenses for the practice of anatomy to certain legally-qualified persons, to appoint inspectors of anatomical schools, and to direct what district each inspector shall superintend. The inspectors are required to render quarterly returns "of every deceased person's body that, during the preceding quarter, has been removed for anatomical examination to every separate place in his district where anatomy is carried on, distinguishing the sex, and, so far as it is known at the time, the name and age of each person whose body was so removed. The practice of anatomy is allowed only to certain specified persons after due notice to the proper authorities of their intention, and on the condition that their rooms shall always be open to the inspector of the district. That portion of 9 Geo. IV. chap. 31 which directs that the bodies of murderers may be dissected is repealed, and it is provided that such bodies shall be hanged in chains or buried within the prison precincts, according to the direction of the court.

The specifications as to what bodies may be legally delivered for dissection are found in Sections VII. and VIII., as follows:—

"VII. *And be it enacted* that it shall be lawful for any executor or other party having lawful possession of the body of any deceased person, and not being an undertaker or other party intrusted with the body for the purpose only of interment, to permit the body of such deceased person to undergo anatomical examination, unless, to the knowledge of such executor or other party, such person shall have expressed his desire, either in writing at any time during his life, or verbally in the presence of two or more witnesses during the illness whereof he died, that his body after death might not undergo such examination, or unless the surviving husband or wife or any known relative of the deceased person shall require the body to be interred without such examination.

"VIII. *And be it enacted* that if any person, either in writing at any time during his life, or verbally in the presence of two or more witnesses during the illness whereof he died, shall direct that his body after death be examined anatomically, or shall nominate any party by this act authorized to examine bodies anatomically, to make such examination; and if, before the burial of the body of such person, such direction or nomination shall be made known to the party having lawful possession of the dead body, then such party shall direct such examination to be made, and, in case of any such nomination as aforesaid, shall request and permit any party so authorized and nominated as aforesaid to make such examination, unless the deceased person's surviving husband or wife, or nearest known relative, or any one or more of such person's nearest known relatives, being of kin in the same degree, shall require the body to be interred without such examination."

In subsequent sections it is provided that no body shall be removed from the place of death to a dissecting-room until after forty-eight hours from the time of death of the deceased person, nor until twenty-four hours' notice, to be reckoned from the time of such decease, shall have been given of the intended removal to the inspector of the district, nor unless, previous to the removal of the body, a certificate stating the manner or cause of death, signed by the physician, surgeon, or apothecary in attendance upon the deceased in his last illness, shall be delivered with the body to the party receiving it for anatomical examination; that persons receiving a body, as above stated, must within twenty-four hours of its receipt transmit the certificate received with it to the inspector of the district, together with a return stating at what day and hour and from whom the body was received, the date and place of death, the sex, and (as far as is known at the time) the Christian name and surname, age, and last place of abode of such person; that every such body shall, before removal, be placed in a decent coffin or shell, and be removed therein, and after undergoing dissection such body shall be decently interred in consecrated ground or in some public burial-ground; that a certificate of the interment of such body shall be transmitted to the inspector of the district within six weeks after the body was received. Offenders against the provisions of this act are to be deemed guilty of a misdemeanor, and are liable to punishment by imprisonment for not more than three months, or by a fine not exceeding £50, at the discretion of

¹ Concluded from page 29.

the court. Actions or suits under this act must be brought within six months after the cause of action accrued.

The act of 1832 is the one still in force. It has served to suppress "resurrecting," and under it the English anatomists seem to have been fairly well supplied with subjects. The following-named amendatory acts have been passed: 4 and 5 Will. IV. c. 26; 21 and 25 Viet. c. 95; and 34 and 35 Viet. c. 16. The most noteworthy amendment is that of 24 and 25 Viet. c. 95, 1861, repealing the provision which allowed the hanging in chains of a murderer's body.

It is no less certain that the German and French schools of anatomy outrank the British than that the latter outrank the American. While it would be of interest to consider fully the subject of German laws relating to anatomy, we are obliged to give what might seem an undue prominence to the French laws, owing to the fact that it is well-nigh impossible to find in this country any but the most meagre sources of information regarding the statutes and police regulations of Germany. If it were necessary, one might, from sources to be found in the libraries of Washington, Boston, and Baltimore, trace the entire development of the French laws concerning the cadaver; but we shall content ourselves with the consideration of some of the more important modern French acts. The universities, the faculties of medicine, and all other learned bodies in France were suppressed by the revolutionary decree of August 18, 1792. Medical science fell into anarchy, and the degree of M. D. became as worthless as it is in many parts of America to-day, although in 1794 *écoles de santé*, as they were called, were established at Paris, Montpellier, and Strasbourg, which had been the head-quarters respectively of the three Facultés de Médecine. The organization of the instruction and police of these écoles was effected under a decree of July 2, 1796, when regular examinations were established. By the terms of this decree pupils during the winter semester were required to receive practical instruction in anatomy and surgical operations from seven till ten A. M. and from five till nine P. M. In 1803 a law to reform and to regulate medical education and practice was passed. The dissecting-rooms had already been put under state supervision. A decree of the executive directory, given September 25, 1798, forbade the opening of any dissecting-room, either public or private, or of any anatomical laboratory, without the consent of the central bureau of the commune in addition to that of the municipal authorities; and made it obligatory on every one having the right to practice dissection to register his name with the commissary of police of his district, to observe all formalities prescribed by the police in procuring subjects, and to designate the place where he proposed to dispose of the *débris* of *cadavera dissecta*. In 1799 the prefect of police in Paris was particularly charged to inspect the dissecting-rooms of the city. The ordinance of the Prefect Dubois, issued October 17, 1803, is said to have been the first of the sort. This ordinance provided that there should be daily fumigation of all the rooms constituting an anatomical theatre; that dissections should begin on the 25th of October and end the 25th of April; that bodies of persons dying of a contagious disease should not be dissected; and that subjects should be carried to the amphitheatres in covered vehicles, and with all due decency. In 1813 the private dissecting-rooms in Paris had increased

in number to forty. The ordinance of the prefect of police, issued October 15, 1813, suppressed all private anatomical laboratories, forbade all dissections or operations upon the cadaver in hospitals, almshouses, private hospitals, infirmaries, houses of detention, etc., and provided that dissections should only be allowed in the pavilions of the Faculté de Médecine and in the amphitheatre of the Hôpital de la Pitié. Under this ordinance the bodies of all persons dying in hospitals, almshouses, etc., including those which had been opened in the course of post-mortem examinations, were deliverable for dissection. The only bodies of the class alluded to which might not be given up for dissection were those of persons dying in the clinics of the faculty and those which should be claimed by friends willing to pay for their burial. The cemetery of the Clamart was designated as the burial-place of all the *débris* resulting from dissection; and every one engaged in the delivery or transportation of subjects, either to the amphitheatres or to the cemetery, was enjoined to observe a becoming decorum. From nine to ten o'clock at night was the hour set for carrying subjects, in covered vehicles, to the amphitheatres. Article I. of the decree of the Conseil général des Hospices, April 28, 1819, declares that "the hospitals shall furnish four hundred subjects to the École de Médecine for the teaching of anatomy and dissections, to wit, for the course of anatomy given by the professors thirty, for dissections from October 1st till April 1st three hundred, and for the course of operations and the examinations during the scholastic year seventy; to the Collège de France, for the chair of anatomy, thirty subjects, and to the Jardin du Roi thirty subjects." The ordinance of 1813 has since been amended and amplified, notably in 1815, 1825, 1832, and 1834, but so far as we can learn has not undergone radical change.

Since November 1, 1879, aspirants to the degree of M. D., in France, have been subject to the decree of the Council of State, passed June 20, 1878. The general features of this law were considered in the Educational Number of the JOURNAL, pages 384-85; but such as have reference to anatomy may be specially noted here. Practical exercises in the laboratories, dissection, and residence near a hospital for a prescribed period are made obligatory. The charge of one hundred and sixty francs for the material used in practical studies is distributed as follows: sixty francs the first year; forty francs the second year; forty francs the third year; twenty francs the fourth year. This tariff superseded that established by the ministerial decrees of August 4, 1869, and April 21, 1869. Under the abrogated tariff students inscribed with the faculty paid twenty francs for each year's dissections, while foreigners paid sixty francs; and the annual charge for practicing surgical operations on the cadaver was a fee of ten francs for enrolled students, fifteen francs for native students not enrolled, and thirty francs for foreigners not enrolled. From the statistical reports of 1876, the latest that are accessible to the writer, it appears that 4852 students were enrolled in 1876 in the Faculties of Medicine of Paris, Montpellier, and Nancy, besides 772 students of medicine in eighteen preparatory schools of medicine and pharmacy. Three thousand four hundred and sixty-three subjects were delivered according to law at the anatomical theatres of the above-mentioned faculties and schools, which had in all 5624 students. The proportion of subjects to students varied considerably.

The Faculty of Paris, for instance, with 4295 students, had 1998 subjects at its disposal; while the École préparatoire de Médecine et de Pharmacie of Lyons, with 175 medical students, received 220 subjects, that of Amiens, with five medical students, had 20 subjects, and that of Toulouse had 80 subjects for 62 students. The following detailed statement is found concerning the distribution of the subjects delivered to the Faculty of Paris. There were delivered for the first and second examinations for the doctorate 532; for dissections, 138 from January 1st till March 31st; and 145 from October 20th till December 31st; for operative surgery, 78; *concours de l'adjurat et du prosectorat*, 47; to the professors, 56; to the prosectors, 80; to the aids of anatomy, 154; 62 were beyond use; 106 were delivered in August and September; and children and embryos to the number of 600 were not used. Total, 1598. Dissections begin, in Paris, from the 15th to the 20th of October, and close March 15th; during which period they occupy from twelve M. to four P. M., six days in the week. The course in operative surgery extends from May 1st till the 8th or 15th of June; from one to three P. M. being devoted to it three days in the week. The number of students engaged in dissection in Paris in 1876 was 761, and in surgical operations on the cadaver 195.

Since the cession of Alsace to the Germans, the Faculty of Medicine of Strasbourg has been replaced by that of Nancy, which in 1876 had 144 students. It had a professor of general anatomy, one of pathological anatomy and physiology, and one of histology. There were connected with its École pratique, a *chef des travaux anatomiques*, a prosector, an assistant in anatomy, an assistant in pathological anatomy, two servants of anatomy, a servant of anatomy and histology, and a laboratory man. One hundred and thirty-two students were enrolled in anatomy, 52 in operative surgery, and 52 in pathological anatomy. The hours for dissection were from eight to eleven A. M., and from one to five P. M., six days in the week, during the winter semester; those for operative surgery were from four to five P. M., twice weekly, during the summer semester; while the hours from two to four P. M., six times weekly, throughout the winter semester were given to practical exercises in pathological anatomy. Seventy-eight students dissected 76 subjects, and 45 bodies were utilized in the practical course in operative surgery.

By a law passed December 11, 1875, the erection of a new École pratique for the Faculty of Paris was authorized at an estimated cost of 4,740,000 francs; the expense to be shared by the city of Paris and the state. Six amphitheatres in the new school take the place of one in the old, and the number of 80 dissecting-tables in the old has been increased to 180 in the new school.

It is impossible, on the basis of such documents as the writer has been able to find, to give any detailed statement concerning the laws which regulate the organization and maintenance of the German institutes of anatomy. The Germans may be more stringent in their demands for evidences of anatomical knowledge on the part of students and more generous in supplying facilities for its acquirement than are their rivals the French; but it must be said that they furnish very little documentary proof to substantiate their claims. We must content ourselves with a brief notice of two German laws. In accordance with a "Students-Hof-

commissions Decret vom January 19, 1810," candidates for the degree of doctor of surgery in Austria, seventeen years ago, were required to make two surgical operations on the cadaver as a part of their examination. The operations were made in the anatomical lecture-room, in the presence of the dean of the faculty, the professors of anatomy, surgery, and ophthalmology, the students in medicine and surgery, and of such experts as might choose to attend. Two tickets having been drawn from an urn containing the names of all the principal surgical operations, including those on the eye, the director read aloud the names of the operations to be performed by the candidate. The candidate had then to explain the nature of the operation, choose from the methods then or formerly in vogue the one he would employ, and defend his choice. In making the operation he was required to use every precaution and appliance which would be employed in an operation on the living body.

In the *Medicinisches Correspondenz-Blatt des württembergischen ärztlichen Vereins*, Bd. xxxiv., No. 1, January 9, 1864, there is given the text of a ministerial decree concerning the delivery of dead bodies to the anatomical institutes of the kingdom. Precise provision is made for dividing the kingdom into districts, and the dead of certain districts are allotted respectively to the universities of Tübingen, Stuttgart, Ludwigsburg, and Ulm. Certain formalities are prescribed as necessary in the transportation and delivery of subjects for anatomical purposes. The bodies which may be dissected are those of executed criminals, of suicides, except in the case of insane suicides, and of all unclaimed dead, without respect to age, whether paupers or convicts, whose burial charges would fall upon the public. The writer would gratefully receive any information of authentic sources of German laws on anatomy.

The most recent statement noticed regarding the facilities for anatomical studies in Germany is contained in a French report, published in 1879, on the University of Bonn and Higher Education in Germany. M. Edmond Dreyfus-Brissac declares that the new anatomical institute at Bonn, which was recently built at a cost of 329,200 marks, is a veritable palace. Its annual budget is 18,204 marks, of which sum 7155 marks are expended in salaries, and 11,049 marks for material; 3000 marks were paid, in 1878, for subjects, and 2000 marks for instruments, in which year sixty-four bodies were at the disposal of sixty students.

Beyond the statistics given in the first article of this series we have no authentic data on which to base an accurate comparison of the amount of dissecting required in American and European schools, and the expense entailed thereby. It is safe to say that no medical school in the United States combines the rigid requirements of Vienna and Prague of seventy years ago with anything like the wealth of opportunity offered at Paris and Bonn to-day. One who should desire to become a thoroughly expert anatomist through dissection of the dead rather than by mangling the living would be justified in going from America to Germany or France simply on grounds of economy. The depopulation of American medical colleges, owing to such a cause, need, however, not be feared so long as the present public and professional indifference to ignorance of the fundamental facts of medical science obtains.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF CHILDREN

BY D. H. HAYDEN, M. D.

ON CATARRH OF THE STOMACH IN CHILDREN.¹

GASTRO-INTESTINAL disorders in babies and young children are perhaps the most common derangement set up by changes of temperature, and in older children a gastric or intestinal catarrh or a combination of both is a sufficiently familiar consequence of exposure to cold. In the child we meet with every variety of gastric catarrh, from the severe acute attack with high fever, which is comparatively rare, to the more common subacute non-febrile gastric trouble, which is milder in character and quickly subsides. Even in children it is exceptional for acute gastric catarrh to be accompanied by pyrexia; therefore, in cases where fever is a prominent feature in the derangement the diagnosis is sometimes difficult.

As illustrative of this last variety of gastric catarrh the author reports a case in a young girl aged six years. It was seen first by him on the seventh or eighth day of the illness, when the ordinary eruptive fevers could be excluded. The diagnosis lay between acute tuberculosis, typhoid fever, and acute gastric catarrh. The occurrence of fever, with a history of previous delicacy of health, was quite in keeping with the ordinary course of tuberculosis. There was, however, no family history of any such complaint, and this important fact, together with the complete absence of distress or anxiety in the expression of the child, and the absence, also, of any œdema of the lower extremities, was held to be sufficient evidence to exclude the presence of this formidable disease.

Between typhoid fever and acute gastric catarrh the distinction was more difficult. The temperature had not followed the typical course of enteric fever, but in children this latter disease is often mild, and its temperature curve frequently deviates from the ordinary type. It was too early to lay any stress on the absence of rose spots, and these are sometimes absent altogether in undoubted cases of typhoid. The state of the spleen was doubtful. In favor of acute gastric catarrh was the slight snuffling, the mild sore throat, the complete absence of delirium or of apparent discomfort, and the irregularity of the fever. It was impossible, however, to exclude typhoid fever, but on the following day (the eighth or ninth) the temperature fell, and decided the question in favor of acute gastric catarrh. Cases of recurring gastric catarrh are far from uncommon, and their diagnosis is more easy. These attacks, where the intervals between them are short, may exercise a very deleterious influence on the health and development of the patient. Such cases are often supposed to be cases of consumption.

The report of a case of the recurrent form of acute febrile gastric catarrh in a young girl seven years old is then given. In this case jaundice, which, in children, in the large majority of cases, is catarrhal, occurred with the last two attacks of fever, and helped greatly to explain the nature of the attacks. In her most recent illness, too, a new feature had been noticed in the diarrhœa which had followed upon the jaundice, and had still further delayed convalescence. In this diarrhœa the characters of the stools, which contained mucus and blood, and were passed with straining and

pain, pointed to a catarrh of the lower bowel. Explaining then the earlier attacks in the light afforded by the later, the conclusions arrived at by the author were that the child's sensitiveness to changes of temperature showed itself in the form of repeated attacks of acute gastric catarrh, accompanied by fever. Catarrh of the stomach unaccompanied by fever, "perhaps the commonest derangement to which children are exposed," is then described, and the treatment of both the febrile and non-febrile forms given, being the same in both cases. We must first do our best to remove all sources of irritation. The acrid mucus, a free secretion of which is one of the ordinary phenomena of the catarrhal state, quickly induces an acid change in the more fermentable articles of food. Therefore, if the stomach is oppressed by sour matters, as shown by uneasiness at the epigastrium, or sour smell from the breath, and a feeling of nausea, immediate benefit will be derived from an emetic dose of ipecacuanha wine. Afterwards a draught composed of tincture of nux vomica with bicarbonate of soda in water, sweetened with spirits of chloroform, taken two or three times a day, will soon restore the gastric mucous membrane to a healthy condition. Strong purgatives must be avoided, but an occasional mild aperient will be required, such as the compound licorice powder or castor oil. If there be fever which does not subside after the action of the emetic, the child may be allowed to take fluids from time to time in moderate quantities. The best are unsweetened barley water flavored, if desired, with orange flower, toast water, or fresh whey. During the treatment, as long as any signs of acidity of stomach persist, great care must be taken to exclude from the diet all matters capable of favoring the tendency to fermentation of food, and even for some time afterwards starches and sweets must be taken sparingly.

The above measures will effect a considerable improvement, but at this point the treatment may be said only to have begun. The patient is in a weakly state from successive attacks, and we have to adopt means to strengthen the digestive powers. A common practice in such cases is to administer the preparation of the phosphates of iron and lime known as "Parish's chemical food." This practice is pernicious on account of the syrup, in which the phosphates are dissolved, supplying materials for fermentation, each dose being soon followed by flatulence and acidity, so that the medicine really aggravates the mischief which it is intended to allay. The better plan is to give dialyzed iron, or, if there be any tendency to acidity remaining, the ammonia citrate of iron with a few grains of bicarbonate of soda sweetened with aqua chloroformi. After a time a change may be made to a solution of strychnia with the perchloride or permanganate of iron, given directly after food. During the same time a mild aperient should be given every few days, whether it seems to be required or not, to insure a proper relief to the bowels, and prevent the retention of any excess of mucous secretion.

In spite of this treatment, however, the child will not be secure against relapses unless special precautions be taken to guard the body against chills. The catarrhal state, whatever be the organ affected, tends constantly to repeat itself under the influence of slight causes, and there is little doubt that it induces an extreme sensitiveness to changes of temperature. A broad flannel binder is recommended to be worn

¹ Enstace Smith, M. D., F. R. C. P., London Lancet, November 20 and 27, 1880.

such children, applied tightly to the abdomen, so as to reach from the hips to the armpits, and the medical practitioner should look upon it as his first duty in these cases to see that it is properly applied. The binder should be considered as a part of the child's ordinary dress, and be cast off at night with the rest of his clothes. In many cases it is necessary, in addition to the above precautions, to fortify the resisting power of the child by cold bathing. Some circumlocution, however, is often necessary in recommending this step to parents. There is a method by which the most delicate child may take a perfectly cold bath with safety and advantage. The method consists in first stimulating the skin by friction, so as to enable the body to resist the shock of the cold douche, and then in lessening the shock itself by placing the patient in hot water. Thus, if a child, on rising from its bed, be well shampooed over the whole body, but especially over the back and spine, and be then made to sit in a few inches of quite hot water, a good douche of cold salt water over the shoulders will have a highly invigorating effect, and be followed by immediate reaction. After being dried the body may be rubbed with flesh gloves, and afterwards, if thought desirable, the child can be returned for a short time to his bed. Before beginning the process the patient should take a little bread and butter, or a drink of milk. The continued use of this bath, besides having a remarkably tonic effect on the system generally, confers great resisting power against changes of temperature, and considerably reduces the child's susceptibility to chills. Thus most obstinate cases of gastric catarrh may be treated with success, but success depends upon equal attention to all the points. A flannel binder will be of little value if the tendency to fermentation be encouraged by the immoderate use of starches and sweets, and even cold douching may not be sufficient to neutralize the ill effects of rapid changes of temperature acting upon a body imperfectly protected from the cold. In all cases it is advisable to avoid the use of syrups in making medicines palatable to young children. The Pharmacopœia syrups are not well borne by young subjects, and often do more harm than good. It is far better to sweeten a child's physic with glycerine or a few drops of spirits of chloroform.

LARGE HEADS IN CHILDREN.¹

The text to this lecture was afforded by two children in the hospital. While rare to be consulted by adults, it is not uncommon for children to be brought for an opinion about their heads, which are thought to be too big, and to indicate water on the brain. Owing to the rapid growth of the brain in childhood the cranium of the brain pan grows much more quickly than the face and the rest of the body, and hence the skull is often wrongly deemed to be unduly large, even in a perfectly healthy child.

When asked for an opinion about a big head the first thing to do is to study, not its size, but its shape. For this purpose the cystometer is a great help, and gives an exact outline of the head in any plane. The longitudinal vertical plane, which passes through the tuber occipitale, sagittal suture, and nasal eminences, is the most useful, the cystometric tracing passing from the deepest part of the nape of the neck, just below

the tuber occipitale, over the top of the head to the deepest part of the bridge of the nose, a little above the canthus internus of the eyelids. The shape of a natural head on this plane is that of an irregular pentagon with curved sides. The fifth side, belonging partly to the face, is somewhat of a constant, not changing with the cranial changes, and may be called the base line, inasmuch as it is a straight line joining the deepest part of the nape of the neck with the deepest part of the bridge of the nose, and corresponds roughly with the base of the skull. The greater number of big heads retain the pentagonal shape. Some do not. The former are called long heads, or *dolichocephalæ*, and the latter round heads, or *cyclocephalæ*. After describing the changes which lead to the long head, the author states the following propositions:—

(1.) The big brain in most cases is naturally big. It does not afford any signs of disease, either during life by lesion of functions, or after death by lesion of structure. The person has a head and brain too great for his body: that is all we have to say of him, but that is saying much, because it is saying that he is not suffering from the incurable disease which is always supposed in such cases.

(2.) The big brain is sometimes unnaturally big: it is said to be hypertrophous. Its functions during life are much impaired. Yet the naked eye cannot detect any structural changes after death. Some there are who affirm that hypertrophy of the brain is due to "diffuse interstitial hyperplasia of the neuroglia;" it would seem to be more agreeable with our present knowledge neither to affirm nor to deny this. For hypertrophy of the brain is an uncommon disease. One case that came under the author's care is here reported, with autopsy.

(3.) But in by far the greater number of dolichocephalæ which the author has examined the brain has not been larger than natural. Wherefore, in such cases, the brain does not fill the skull, and the space between them is occupied by serum. The effusion is both external and internal; it seems to be passive, simply filling up what would otherwise be a vacuum. Nor are there any signs of pressure, either upon the skull or the brain. In these particulars this kind of hydrocephalus, or water on the brain, differs altogether from the active hydrocephalus, which is ventricular or internal, which dilates the skull by equal pressure in all directions into a sphere, and which also compresses the brain. Most, if not all, of these children are rickety, as was well known by the earliest writers on rickets, as several citations by the author show.

The manner in which the head is enlarged by syphilis is then described. The enlargement is never great, and the big head, such as it is, is indicative, not of a cranial cavity larger than natural, but only of a thickened skull. The head of syphilitic children often possesses all the characters of the rickety head, and the author has always deemed these children both syphilitic and rickety, and has even gone so far as to believe that syphilis may be looked upon as a cause of rickets, though stoutly denying the doctrine of Parrot that it is always the cause.

In round heads the shape ceases to be a pentagon, and becomes a segment of a circle. Cyclocephalus is the shape proper to ventricular hydrocephalus, a disease characterized by an active distention of the ventricles of the brain by serum, and a much more serious

¹ Clinical Lecture delivered in St. Bartholomew's Hospital, June 4, 1880, by Samuel Gee, M. D., F. R. C. P., London. *Lancet*, September 15, 1880.

disease than the passive hydrocephalus above referred to. Hydrocephalus does not produce a round head after the fontanelles are closed and the sutures well united. Acute ventricular effusion, occurring in tubercular or purulent meningitis, does not produce a round head, even when the fontanelles and sutures are not closed; the pressure, we may suppose, does not last long enough. The peculiar change in the position of the eyeballs with respect to the eyelids, a condition due to excessive obliquity and drawing upwards of the orbital plates, a well-known effect of the active distention of the skull from within by fluid, is never met with in dolichocephalus. Optic neuritis going on to atrophy of the disks is sometimes caused by hydrocephalus, especially when it sets in after the fontanelle has closed. When the head admits of distention and becomes cyclocephalic the optic neuritis is often absent. In extreme hydrocephalus the head is sometimes seen to be translucent in a strong light, such as that of the sun.

(To be continued.)

Hospital Practice and Clinical Memoranda.

FRACTURES OF BOTH FEMURS, OF THE LEFT TIBIA AND FIBULA, OF THE RIGHT HUMERUS AND RIGHT RADIUS, WITH RIGHT RADIO-CARPAL DISLOCATION, IN THE SAME SUBJECT; RECOVERY.

BY F. N. GIBSON, M. D., NEW IPSWICH, N. H.

BESSIE S. H., of T., aged eight years, nervous temperament, spare build, active habits, while at play, October 18, 1880, near a perpendicular shaft in motion, was caught thereon by her clothing, and carried around at the rate of from one hundred and fifty to two hundred times per minute, till the machinery could be stopped.

I saw her about three hours after the accident: found the pulse feeble, eyes bloodshot, and the patient, although suffering greatly from shock and injuries, perfectly conscious. Stimulants were given, and as hospital advantages were inaccessible preparations were at once entered into for home treatment.

A hard husk mattress was placed upon an unyielding bedstead, and pulleys fastened to the foot of the bed. Upon this mattress, suitably covered with linen and rubber cloth, the patient was placed, and ether (Squibbs) administered by Dr. G. F. Munsey, of Greenville, who kindly assisted in caring for her during the first four days.

Anæsthesia was readily produced, and I found she had sustained the following injuries, namely: (1.) Oblique fracture of right femur, middle third. (2.) Transverse fracture of left femur, middle third. (3.) Transverse fracture of left tibia and fibula, middle third, (slightly comminuted). (4.) Transverse fracture of lower third of right humerus. (5.) Fracture of lower third of right radius. (6.) Partial right radio-carpal dislocation. There was manifestly much injury sustained by the soft parts at seat of fractures, particularly upon the thighs and arm, and there were several contusions and abrasions of the skin over other parts of the body.

Splints were prepared from leather board, adapted to each fracture, and covered with a few layers of soft linen; strips of rubber adhesive plaster, extending along both sides of the legs and well up on the thighs,

were connected with the weights by cords passing over pulleys, with which extension was made, the foot of the bed being elevated four inches. The fractures and dislocation were all adjusted without great difficulty. Dry compresses, splints, and roller bandages, with sand-bags for lower extremities, completed the dressings.

As might be expected, the general system suffered greatly from shock and the extensive injuries sustained. Stimulants were administered freely during the first twenty-four hours; almost complete syncope occurring several times.

Second day. Reaction and strengthening of pulse. Frequently awakes from sleep with a scream and look of terror and fright, and general muscular contraction. Tincture of camphorated opium combined with atropia, alternated with chloral hydrate and bromide of potash, were given and continued as required for five days. Third day. One convulsion, lasting three minutes; surgical fever not unexpectedly high. Fourth day. Much complaint from effects of involuntary passing of urine, which had completely saturated bandages of thighs. Fresh bandages and clean linen were consequently applied. To obviate this annoyance in future, pieces of rubber cloth, extending above the bandages and below the knees, were fastened together separately at the upper ends. Some excoriation upon the nates, to which vaseline and subnitrate of bismuth were applied. Sixth day. Fresh dressings to leg and arm; not an undue amount of surgical fever. Eighth day. Passing of urine not entirely involuntary. Failed in the use of various urinals, till we tried a piece of lead pipe, beveled at one end and closed at the other, of which we made use till patient left the bed, with good success. Ninth day. Swelling abating, so that bandages upon thighs are loosened; clean dressings applied. Probably owing to some injury to the nerve trunk, there has been daily considerable spasmodic muscular contraction of the right thigh, shortening the limb an inch or more, and allowing no union, which seems to be taking place in all other fractures. Twelfth day. Only two spasmodic displacements of right thigh; these were the last. Fourteenth day. Fore-arm, leg, and both thighs dressed; swelling much abated; excoriations and abrasions, to which soap-suds, vaseline, and subnitrate of bismuth have been applied, are mostly healed. Sixteenth day. Right thigh does not shorten on removal of extension, and shows first indication of union. Twenty-eighth day. Splints (lateral) removed from fore-arm. Forty-second day. All splints and dressings have been removed from arm and leg. Weights and pulleys removed, and plaster-of-Paris bandages applied to the thighs, firm union having taken place. There is neither ulcer nor excoriation anywhere upon patient, who now commences to sit up in bed and in a chair.

Careful measurements have been made almost daily from the first, and great attention given to retention of lower limbs *in situ*. Owing to the active habits and great restlessness of patient, I early found it necessary, in order to retain the parallelism of thighs with the pelvis, to somewhat confine the body, which was accomplished by placing a block of wood upon either side under the mattress, making a trough, out of which she could neither roll, wriggle, nor twist.

Fifty-sixth day. Plaster-of-Paris bandages loose, and are removed, and starch bandages substituted. Simple but nutritious diet has been allowed; the bowels moved

by compound licorice powder when diet and fruit failed to keep them sufficiently open. Patient sits up nearly all day, and looks as robust and healthy as previous to the accident.

Seventy-eighth day. Saw patient to-day, who is now recovering from an attack of measles. She presents no indication of deformity, and has firm bony union in all fractures: with the single exception of slight tilting upward of lower extremity of the upper fragment of left femur, there is complete coaptation of all fractures, and as this fracture was transverse there is no perceptible shortening.

To the parents, who have acted as nurses, and have been unceasing in their care and attention, is largely due any credit deserved for so successful a recovery.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

JANUARY 10, 1881. DR. JAMES C. WHITE, permanent chairman, presided.

OVARIOTOMY.

DR. JOHN HOMANS gave an account of twenty consecutive cases of ovariectomy operated on during the past twelve months. Vide page 50 of the JOURNAL.

DR. CHEEVER said that we all must feel much gratified with the success of Dr. Homans's cases.

Twenty-five years ago he twice saw the abdomen opened to remove ovarian tumors, with a fatal result. These cases occurred while he was a student. The operation fell into disuse in Boston, and was discouraged by many physicians. The coming of Mr. Spencer Wells in 1867 gave a new start to ovariectomy. Up to that time there had scarcely been a successful case in this city, certainly none in the hospitals. Subsequently, in 1872, he saw Mr. Wells operate, and his after-treatment, repeatedly in London. Returning to Boston, Dr. Cheever had two cases of recovery in succession in 1873. This gave him encouragement; and he had since operated with varying result. He had twice been so unfortunate as to meet with soft cancer of the ovary. In these cases there was fluctuation; and they illustrated the fact that it was impossible to distinguish by palpation the quiver of a soft solid from true fluctuation. Fibro-cystic tumor of the uterus and a suppurating cyst had twice given him fatal results. Latterly he had used the Lister method, the cautery, and the replacement of the stump in the abdomen, with perfect success.

He believed the patient's chance of living depended largely on the activity and vigor of her organic or nutritive powers. It was often a question of stock. Those who had good constitutions and good stomachs recovered from surprising mutilations. He had operated on an abdominal tumor where a large section of peritoneum was necessarily cut away, and the bowels closed in only by a flap of dissected skin, and the patient recovered. This was before the antiseptic method.

He thought replacing the pedicle in the abdominal cavity much superior to the clamp. The latter always gave after-pains (uterine) from traction. Haemorrhage from the uterus he had very frequently noticed after ovariectomy.

The division of adhesions by the cautery was a great improvement. He thought ventral hernia an exceedingly common sequence of abdominal incisions, and asked if others had not found it so.

In answer to questions by Dr. Fifield, Dr. Homans said that, in regard to feeding, until lately he had only given flour gruel during the first forty-eight hours after the operation, that he was not now so particular in this respect, and that he always had an enema given on the night previous to the operation, and solid food allowed as soon as the patient passed wind freely.

DR. HOMANS did not approve of administering morphia subcutaneously on account of its depressing effect; if it was necessary to employ opium he gave it by the rectum, but he seldom used it, and relied on hot ginger.

DR. BIXBY said he had been intensely interested in Dr. Homans's paper. He had been engaged in the study of ovarian disease and ovariectomy for many years. The contrast in the repute of the operation and of the operators twenty-five years ago and at the present time was most striking.

No department of surgery had made greater progress. Illustrative of this, in connection with Dr. Homans's experience, in 1857, he had seen a patient brought into the amphitheatre of the Massachusetts General Hospital for ovariectomy; he thought it must have been the same case referred to by Dr. Cheever.

A small incision disclosed what seemed to the operator to be extensive adhesions. After due consultation by the three or four surgeons present, the case was accounted a *noli me tangere*. The wound closed, and the patient returned to the ward. He should never forget the look of doubt depicted upon their countenances.

DR. BIXBY further stated that during the last twelve years he had performed ovariectomy with and without success before the days of antiseptic surgery. It had been his good fortune to witness the operation more than a hundred times. In a large number of these cases he had conducted the after-treatment, and in at least twenty-five cases, for the sake of the practical experience, had acted in the capacity of nurse.

In review of this extended and most instructive experience, in which all the different methods of operation, course, and results have been practically demonstrated, he looked back with regret that this wonderful discovery had not sooner dawned upon us. While there were many cases, undoubtedly, which might have been saved by this method, brilliant results were not infrequent long before this event, and under the most unfavorable circumstances. To illustrate, a patient, aged seventy-five, with double ovarian disease of long duration, was ruptured by a fall. On making an incision the parts were found universally adherent, the abdomen was exposed to the air for nearly three hours, large portions of peritoneum and omentum were removed, and nineteen ligatures left in the abdominal cavity, yet the patient recovered as if from the most simple illness. Again, in these times of antiseptic surgery he had seen the simplest case, without adhesions, short incision, not the slightest exposure of the abdominal cavity, die on the fifth day from peritonitis. While being a firm believer in antiseptic precautions in ovariectomy, the skill derived from the accumulated knowledge of the conditions of the pelvic and abdominal viscera should not be underrated in our estimates of diminished mortality in ovariectomy under the new departure.

CEPHALEMATOMA.

In reply to a question by Dr. Reynolds as to the best treatment of cephalematoma, and to some remarks of Dr. Fiffeld in favor of the treatment by opening freely, Dr. Fitz said that the dangers generally admitted as likely to follow a free opening were putrid absorption from the exposed surface and necrosis. To these might be added in the present instance the probability of hemorrhage on account of the jaundiced condition of the infant.

The increase in the size of the tumor since birth indicated that hemorrhage was still taking place, and it would therefore seem injudicious, for the present at least, to make an incision into the sac.

The reports of recent cases of this affection were not such as to encourage attempts at a rapid cure by means of a free opening, but in the absence of special symptoms favored either non-interference or the use of the aspirator if the blood were fluid.

HYDRENCEPHALOCELE.

Dr. O. W. DOE exhibited a specimen of hydrencephalocele. The case was seen in consultation with Dr. Pattee. The mother was a primipara. The child presented by the breech, and after puncturing, the head was easily delivered by forceps; the head measured twenty-four inches.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

PROLONGED GESTATION AND DIFFICULT LABOR.

MARCH 13, 1880. Dr. HOSMER, referring to an expected labor, reported at the December meeting as overdue, gave the further particulars of the case. He had first seen the patient for epithelioma of the cervix uteri (reported at the meeting in February, 1879, and published in the JOURNAL December 25, 1879), the operation upon which, performed December, 1878, had resulted in complete success, the os and cervix having been restored to a healthy condition. In January, 1879, there was slight uterine flow at two different times, and a regular menstruation began February 15th, and lasted six days. A closed lever pessary was soon placed in the vagina, but produced discomfort, and was at once removed. Conception soon after occurred. Motion continued from June 1st, six and a half months before labor. The patient expected to be confined late in October. Dr. Hosmer had calculated that labor would not be due before the 22d of November. Early in the pregnancy there was much gastric disturbance; later, great pain and discomfort in the pelvic region, and general oedema with sufficiently free secretion of urine. Genuine labor commenced at four P. M., December 16th, and had been supposed to have commenced at two or three different times after December 1st. The patient was delivered December 17th, at 5.20 P. M., the child, a male, still-born. Its weight was 4400 grms. = 9.68 pounds (average 3300 grms. = 7.26 pounds); length 57 cm. (average 50 cm.). The head was firmly ossified, and the fontanelles hardly to be felt. The circumference of the head was 37 cm. (average 34.5); the biparietal diameter 10.5 cm. (average 9); occipito-frontal diameter 13 cm. (average 11.5); width of shoulders 13 cm. (average 11).

The maternal pelvis was somewhat oblique in the superior strait, and the promontory was rather prominent. From March 12th (twenty-six days after the menses commenced) to December 17th was two hundred and eighty days. Dr. Hosmer gave the following detailed history of the labor: The occiput was at the right acetabulum. The early progress of the labor was extremely slow. The forceps were applied and abandoned, such was the sense of unyielding resistance. At this stage of the case the doctor and nurse both heard distinctly a repeated sound, which, seeming to proceed from within the body of the mother, could not be distinguished from, and under the impulse of the moment was declared to be, and is now believed to have been, the cries of the child in utero. Version was next resorted to, and delivery was accomplished with great difficulty. The perineum was torn, and was repaired by two or three sutures. Slight traction was made upon the cord and moderate pressure upon the fundus uteri, but the placenta did not descend, and was found to be adherent. While this was being detached and the effects of the ether were passing off the patient suddenly began to sink, and became extremely cyanotic. There was nausea, and the recurring efforts to vomit caused blood to escape in considerable quantity from the vagina, notwithstanding the fact that the uterus was carefully but firmly compressed by the two hands of the attendant, one being in the cavity of the imperfectly contracted organ, and the other applied to the abdomen. The condition of the patient was alarming, and there was an urgent demand for a stimulating subcutaneous injection. For the purpose of administering that the assistance of a neighboring physician was sought, but before he arrived the woman was tolerably safe. For a few days there was slight elevation of temperature, together with abdominal swelling, tenderness, and more or less pain in the right groin. The catheter was required for ten days. The urine drawn within the first twenty-four hours after delivery was thick, muddy, and highly albuminous. The albuminuria and oedema soon ceased. On the second day the left leg was reported to be heavy and numb, and later was the seat of severe pain from the knee to the ankle, with some contraction in the first-named articulation. These symptoms disappeared slowly. On the night following the eighth day and during the ninth day there were several profuse vaginal discharges, which came in the form of copious gushes of a colorless fluid, which had no smell and left no appreciable stain. This fluid was certainly not urine. A little later there appeared a cystitis, which got better and then became worse, the urine depositing a good deal of pus, but showing no mucus. Urination was rather frequent and somewhat painful. In February a double catheter was employed, and the bladder washed out with a solution of carbolic acid twice a day, and the patient is still under this treatment.

Dr. FOSTER asked why the placenta was removed so soon after the delivery of the child.

Dr. RICHARDSON inquired what advantage there was in pulling on the cord as compared with gentle pressure over the uterus. If the placenta is not adherent gentle continued pressure over the uterus will effect the expulsion in a safer way than traction on the cord.

Dr. HOSMER replied that the Vienna kneading had been discussed and objected to, and asked Dr. Rich-

ardson where he usually found the placenta after expulsion.

DR. RICHARDSON stated that he usually found it half-way down the vagina and caught in the os, and that he preferred to take hold of the placenta rather than the cord. He had never known of the occurrence of inversion, except when traction on the cord had been made in conjunction with pressure on the fundus.

DR. STEDMAN referred to the number of cases on record where inversion had occurred without traction on the cord.

DR. RICHARDSON remarked that he had seen several cases among the students where more or less tenderness over the uterus and pain were complained of, — the result of undue pressure or badly applied pressure over the uterus.

DR. BOARDMAN observed that his recollection of the teaching of the Vienna school, which he had always followed, was that we should employ at first gentle kneading until a full, firm contraction occurred, and then strong pressure in the proper axis. — With this method, there was no danger of inversion or other accidents, the secret of safety lying in waiting for the full uterine contraction.

DR. ABBOT said that he always pulled on the cord wound two or three times about the right hand, — a steady pull, with the left hand on the fundus, — and then seized upon the placenta as soon as it came within reach.

DR. INGALLS asked what would become of the placenta if let entirely alone, to be expelled by the natural efforts, or in what time would the placenta, on an average, be expelled.

DR. REYNOLDS replied that in one hundred cases the average time was found to be forty-five minutes.

DR. INGALLS said that he had never known the placenta to be retained over twenty minutes within the uterus. He further stated that he had never had an adherent placenta.

WARTY VAGINAL GROWTHS OCCURRING DURING PREGNANCY.

APRIL 10, 1880. — DR. RICHARDSON reported the following case: —

E. G., married, twenty-two, primipara, expected date of confinement June 1st, entered the hospital May 24th to await confinement, giving the following history: Had been perfectly well during the whole term of pregnancy until the sixth month, when she noticed a thin yellow discharge from the vagina. This became gradually more profuse, color yellowish-green, and was accompanied by a burning sensation of the vagina and vulva and considerable pain. Patient stated that she had felt no motion of the fetus for the past six weeks, and, feeling alarmed, consulted a physician, who sent her to the hospital for treatment. Examination was immediately made. By palpation the head was found above the pubes, the back to the left of the median line.

Auscultation discovered a distinct fetal heart to the left and below the umbilicus.

Per vaginam. First noticed was a profuse and extremely offensive ichorous discharge. Upon passing the examining finger into the vagina it was found to be filled with warty growths extending from the vulva to the cervix uteri and into both cul-de-sacs. These growths were so numerous about the cervix that the os was recognized with the greatest difficulty.

The patient suffered intensely, the warts being so sensitive that the least touch caused her to cry out with pain. A Sims's speculum was introduced. The warts were found to resemble syphilitic condylomata in appearance, extending from the mucous membrane into the vagina from a quarter to one half an inch. Both cul-de-sacs were completely packed, the only free surface being a circle about one quarter of an inch deep about the os. In the lower third of the vagina the growths were less numerous, the intervening free surfaces, together with the labia, being excoriated and covered with aphthous patches. The whole vulva was tender and swollen. A vaginal douche of carbolic acid, one drachm to the pint of warm water, applied every two hours was ordered. Under this treatment the discharge became in a few days less offensive and the warts less sensitive.

June 20th. Normal labor, presentation O. L. A. Child, weighing eight and one half pounds, perfectly healthy. The warts at this time had to a considerable extent disappeared, were very little sensitive, and seemed to offer no obstruction to the descent of the head.

June 22d. The warts were found to be breaking up and coming away with the lochia. Convalescence was normal.

July 2d. Os patulous, through which there was a slight sanguineous discharge. The warts had entirely disappeared, with the exception of a few small papules in the posterior cul-de-sac.

DR. FIFIELD said that he did not think the case exceedingly rare. He had found statements of this condition of the vagina in monographs by French writers, as Despres and others, the growths having been developed during pregnancy, and rather suddenly disappearing after labor. Sometimes there is an enormous development of the labia, as in a case he had cited at a former meeting of the society. In this instance the growth had been supposed to be cancerous, but was diagnosed by Dr. Fifield as warty. It was removed without recurrence.

DR. RICHARDSON said that there was an important difference of locality between the case described by him and some of those referred to by Dr. Fifield. He had himself seen a number of cases, in the hospital, of warty growths upon the vulva and extending up into the vagina slightly, but not, as in the present case, invading both cul-de-sacs.

DR. FIFIELD remarked that in special hospitals one sees the granular vagina not always due to gonorrhœa, just as in pregnancy a profuse acute purulent discharge is sometimes met with simulating gonorrhœa. Cases of vaginitis are not necessarily of gonorrhœal origin.

— The Walnut Hill Asylum at Hartford, Conn., for inebriates and opium takers, has been changed to a private institution, on the home and family plan, and is opened for the reception of patients. Dr. T. D. Crothers remains superintendent as before.

— The *British Medical Journal* quotes from a letter on the present state of affairs in Ireland: "I am at present attending at a landlord's house, he being very ill of fever. A doctor from a disturbed district having come to see him professionally, said, by way of comforting the family: 'Faith, its a fine thing for a man to be allowed to die in his bed these times.'"

Medical and Surgical Journal.

THURSDAY, JANUARY 20, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY, BOSTON, MASS.

THE SPRAY IN ANTISEPTIC SURGERY.

THE use of the spray in antiseptic surgery has been receiving critical attention of late from several different quarters, which merit consideration. Its value has been seriously called in question, one writer pronouncing it actually mischievous, and the well-known annoyances inseparable from it have been more fully dwelt upon. Prof. v. Bruns, of Tübingen, in a clinical lecture published in the *Berliner klinische Wochenschrift* for October 25, 1880, under the title of *Fort mit dem Spray*, gives the result of his hospital experience with and without spray. This lecture formed the basis of an editorial article in the *Medical Times and Gazette* of December 18th last, and has been translated in full in several American medical journals.

Prof. v. Bruns was led from a study of the subject to the belief that the employment and need of the spray during operations had not been sufficiently justified, and, indeed, that its use, from a theoretical standpoint, should be considered as an unnecessary addition to the antiseptic treatment of wounds. Putting this belief into practice, he substituted for the spray temporary irrigation — lasting a few seconds only — with a two per cent. or five per cent. carbolic solution. Several times during any long operation, and at the termination of short operations, and in addition at the end of any operation, he washed the whole wound-surface with the stronger solution. He says: "I endeavored by experience, and apart from all theory, to test the value or the worthlessness of the spray; and to this end, in the course of the year 1878, I performed a gradually increasing number of operations without the spray, which I published in 1879. Since this time, and especially since the spring of 1879, I have entirely banished the spray-producer from my wards, doing both my operations and my dressings without it, and experience has confirmed my views entirely. The result of all published major operations undertaken elsewhere *with* the spray, and here *without* it, not only as regards mortality, but also course and duration of the healing process, has proved more favorable in this than in any other hospital. The results are so substantial that they warrant the following assertion: 'The carbolic spray in surgical operations is not only useless and unnecessary, but also disagreeable and productive of interruption: it should therefore be abolished.'"

We offer our readers in our present number an interesting letter from a correspondent in Vienna giving an account of the antiseptic methods which obtain

at present in the hospital practice of Professor Billroth at the General Hospital, from which it will be seen that this distinguished surgeon also has abandoned the use of the spray, with satisfactory results. Reference is made to a paper by Dr. Mienliez, one of Professor Billroth's assistants, where are to be found experiments and calculations by which the writer strives to take the census, and determine the relative prosperity of the bacterial population of the surrounding air and of the wounds with and without the use of spray. Conclusions are arrived at evidently justificatory to the writer of the new faith now in him.

We are induced to call attention to these views about the spray in connection with a very successful series of ovariectomies performed by Dr. John Homans during the past year, a record of which is published in this JOURNAL. These were done with the usual Listerian precautions.

It seems to us that in all such operations as are enumerated by Prof. von Bruns, — none of them involved a cavity or sac like the abdomen, — and, in fact, all external operations the use of the spray is unnecessary if the wounds are thoroughly washed out and syringed out with carbolized water and all the sponges and other articles are also carbolized. But in ovariectomy one cannot wash out the peritoneal cavity two or three times during an operation, and one would not desire to, for it would make such an amount of handling of the abdominal contents necessary as to create, perhaps, peritoneal irritation and rise of temperature. By the use of the carbolic spray in ovariectomy the abdominal contents are kept as pure as air would be in a bottle with a stream of spray playing over the mouth of it. No matter how much a stump or the wound left after an excision of the breast may be washed and syringed, one can leave in a drainage-tube and feel no anxiety; but to wipe all around the liver, stomach, spleen, and all the nooks and crannies of the abdomen, when this may be avoided by the use of the spray, and when we do not wish to put in drainage-tubes, is to subject the patient to an amount of manipulation that is dangerous and unjustifiable. One may dress an external wound as often as one pleases; but the perfection of antiseptic ovariectomy and the very common result is to dress the wound but once, and that at the time that the sutures are removed.

Dr. Mienliez states that "practically the disadvantage of irrigation is that the subsequent discharge from the wound is apt to be greater than when spray is employed, and a more frequent change of dressings is thus necessitated." In all operations, then, except opening any of the great cavities of the body, such, for instance, as opening the thorax or abdomen, we would agree that the spray might be given up and irrigation substituted; but in the operation of ovariectomy the spray is a very essential part of the antiseptic process.

— Dr. Fordyce Barker has been unanimously re-elected president of the New York Academy of Medicine for the ensuing year.

ADULTERATION OF FOOD.

THE Supplement to the National Board of Health Bulletin for January 1, 1881, gives the extended report of Dr. Charles Smart, U. S. A., on his investigation to determine the prevalence of adulteration in food supplies, undertaken in accordance with instruction from the National Board of Health.

This report embraces the results of the examination of two series of samples, one of which was derived from sources whence purity might be expected, and the other from sources which might be presumed to yield low-grade, if not adulterated, goods.

A great deal of sensational writing has appeared from time to time concerning food adulteration, the text of which has mainly been derived from English experience. Loose statements have been made even in official reports, which have fostered the sensational outcry until it has reached such a pitch as to suggest the defeat of its object by creating a prejudice against itself. Compilations from Hassall's book have been published as personal experience, and quoted so often that people have become tired of hearing about food adulteration, and discredit the whole thing, except perhaps that milk may sometimes be watered. Statements of individual facts are required to place the subject on a sound basis, and for this reason, while a general summary of results is presented as the body of this report, there is appended an itemized list of the facts developed during the investigation.

A careful comparison of the results with the facts developed during the investigation by the English committee, twenty-five years ago, shows clearly that food adulteration is practiced in this country at the present time to as great, if not to a greater, extent than prevailed in England at the time of the agitation which led to the enactment of repressive laws. Our corn meal and lard are pure. Our wheat flour is not mixed with alum, but the bakers use it. Our sugars are cleaner, but we have glucose admixtures which the English had not; and if our coffees are better it is owing more to the practice of home grinding, bequeathed to us from the early days of the country, when grocery stores were not so common as they are now. The few samples of loose coffee which were found to be adulterated show that there is a tendency to debase the article, which would no doubt increase as the coffee-mills disappear from our kitchens, until the condition of the market would be represented by the trash which is now sold as package coffee. On the other hand, the remainder of the articles included in this report are found to be in as bad, and many of them, — as the pepper, allspice, cinnamon, etc. — in a worse, condition than were the English supplies when official attention was directed to them.

Fortunately, with such exceptions as the alum in bread and baking materials, the sulphate of lime, which oftentimes replaces cream of tartar in household baking, the debasement of milk by dilution, and the poisonous pigments used for coloring confectionery, the adulterations cannot be considered as deleterious. They affect the pocket of the individual rather than his health, so that, to use the words of the committee ap-

pointed by the National Board of Trade to award prizes for the best draught of an act repressive of adulteration, "the question of adulteration of food should therefore be considered not so much from a sanitary stand-point as from that of commercial interests, as being of the nature of a fraud in aiding the sale of articles which are not what they are represented to be."

There were examined 713 samples. Of these, 304 were obtained from sources which implied purity, and 409 from those which might be considered suspicious. Of the former 24, or 7.89 per cent., were found to be of such a character that under a law repressive of fraudulent adulteration prosecution might have been instituted with full prospect of effecting conviction. Of the latter, 183, or 44.74 per cent., would have been in like manner condemned.

But these percentages, although they appear to give expression to the prevalence of adulterations, in reality convey no meaning. Lard and corn meal were found to be unadulterated. If, instead of a few samples of these articles, enough to determine their general character, a large number had been included in the report, the percentages of impurity would have been proportionately diminished, but the facts would have remained the same. So, had the examinations of ground spices been multiplied, the percentage of impurity would have been increased. To appreciate fully the condition of things the facts relating to each article of supply must be considered separately, as given in the report.

 THE GOVERNOR'S ADDRESS TO THE MASSACHUSETTS LEGISLATURE.

IN the part of the late address of the Governor of Massachusetts relating to state charities several suggestions are made in regard to the provision for and disposition of the insane. The following is pertinent and judicious:—

"I trust that, both as a matter of treatment and economy, some other plan will be adopted than that of erecting another costly hospital [for the insane] like the last. It is desirable that there should be a more intelligent classification of the insane, instead of herding them all together. I see no reason why, taking some of our state or county buildings, which I understand are available for the purpose, separate provision should not be made, for instance, for the criminal insane, a hundred of whom, perhaps, could now be collected apart, thus humanely and justly relieving the others from what they and their friends rightly feel to be a reproach and a constant personal danger, and also relieving the growing pressure of numbers to be provided for in present quarters. I am advised that this classification should be made at an early date. It is also true that among the insane poor are many epileptic patients. Their presence in our hospitals disturbs the discipline and treatment of the ordinary insane, and they might well be placed in a separate establishment, not at present, but whenever a sufficient number shall warrant.

"Other classifications suggest themselves, after all

of which, however, the great body still remains to fill our hospitals. In the treatment of them the tendency is toward less and less restraint, both as a matter of personal right and of cure. An insane man is not often a criminal, and is entitled to personal freedom, except so far as restraint is necessary for keeping himself from harm and others from intolerable annoyance or danger. It is worth considering whether the system, which promises to be so successful, of finding cheap and good boarding-places for young children now at the State Primary School could not be applied also to the harmless insane. Many of these are able to labor, and would derive benefit from employment. Many patients of this class have been thus removed from hospitals in former years, and the same policy might now be further extended, as is done in Scotland and other countries. In that case every needful safeguard should be provided against abuse or neglect of this helpless class. Or, if the numbers increase so that the State should still itself prefer to board them, it could do so in cheap, wholesome tenements, and in the simplest atmosphere of inexpensive and comfortable homes. In either case there must of course be regular visitation and medical oversight.

"Connected with this change of opinion is the suggestion lately made to me, that, if it shall come to the erection of new buildings, these should be small hospitals, where the curables could have every available appliance for their recovery; while, for the incurables, buildings such as I have already referred to, constructed at no great expense, would be found sufficient to meet any exigency for some years to come.

"From all the information that has come to me, it seems that the laws for the commitment and detention of the insane are better understood and more carefully administered than ever before."

We must confess ourselves to be less in sympathy with the Governor's reference to the Board of Health, Lunacy, and Charity, as we continue fully persuaded that it was "hardly worth while" to try the original new experiment of consolidation, especially if it was one of form and not of substance, and no saving in expense was effected. The address says:—

"With regard to the board itself, I trust you will make no change. It embraces two or three subdivisions, formerly kept apart, yet closely affiliated and interdependent. Its work has been well done, and it is hardly worth while to try a new experiment every year or two in the mere form of the central supervision of the interests now intrusted to its charge. I am persuaded that the change of 1879 was rather one of form than of substance, and that any further change, or change back, would be the same."

The possible advantage of a metropolitan sewerage commission is alluded to in the following:—

THE CHARLES AND MYSTIC RIVERS DRAINAGE.

"The continued and increasing use of the Charles and Mystic rivers as reservoirs of sewage will be brought before you by the same board. The foul condition of either stream will be an injury to both

health and comfort in the towns near its mouth, however good their own drainage may be. As it is not possible for any one of these towns to carry out a system of sewerage that is not liable to injure a neighboring town, some sort of concerted action is necessary; and it is suggested that this board or some other competent authority have power to arrange, or at least to report upon, a comprehensive system for draining the entire area embraced within a semicircle of a radius of ten miles from the State House. How great their interest in this matter is appears in the fact that seventeen of them contain more than half the valuation and more than a third of the population of the whole commonwealth."

MEDICAL NOTES.

—Dr. C. F. Folsom has been appointed superintendent of the Danvers Insane Asylum. We have good ground to hope that at length suitable provision will be afforded for clinical instruction in insanity.

—The extent of the provision made for the maintenance of the poor, the sick, and the insane in the State of New York may be to some extent appreciated from the following statement by the Governor: The property, real and personal, held for charitable purposes in the State may be set down in round numbers as follows:—

By state institutions	\$6,900,000.00
By cities and counties	6,200,000.00
By incorporated associations	21,900,000.00
Total	\$35,000,000.00

The total expenditure during the past year for the support of the several charitable institutions, public and private, reached about \$8,000,000. The average number of beneficiaries was approximately as follows:—

In state institutions	4,800
In city and county institutions	15,700
In incorporated and benevolent institutions	24,200
Total	44,700

The total number of insane persons in the several state and local asylums, poor-houses, and private asylums, for the years stated, was as follows:—

October 1, 1880	9543
October 1, 1879	9015
October 1, 1878	8771
October 1, 1877	7921

The rapid increase of insanity is reported as truly alarming, both as to the individuals affected and the necessary provision to be made for their care. The average annual increase of insane for the last four years has been four hundred persons. The Buffalo asylum, which has been so far completed as to accommodate three hundred patients, cost about a million and a quarter of dollars, or more than four thousand dollars for each inmate. Such extraordinary expenditures for the care and treatment of the insane seem to the governor like a profligate use of the public funds. Whatever future facilities may be required for this purpose should, he thinks, be provided upon a much more economical scale.

— We cut the following from the remarks of Mr. Clement Lucas in the debate on Rickets at the Pathological Society of London:—

Children under nine months, suffering from rickets, will almost invariably be found to be bottle-fed, whereas children suffering from rickets at sixteen or eighteen months will often be found still hanging to the mother's nipple. In either case the diet is injudicious, and I will undertake to produce rickets in any child under three years of age that I may be allowed to feed improperly. As regards which child is most frequently attacked by rickets, my experience, in accord with what Sir W. Jenner said on the last occasion, was that the eldest child of the well-to-do and the later children of the poor suffer most. The eldest child of the rich suffers because it is an experimental child, and the parents learn by practicing upon it how best to feed those that follow.

NEW YORK.

— The public hospitals and insane asylums were decorated for Christmas with evergreens and bright cards and pictures, as usual, by the ladies of the New York Flower Mission, who also distributed a considerable quantity of fruit, jelly, beef tea, and groceries among the sick poor in tenement houses.

— In consequence of the crowded condition of the hospitals for small-pox and other infectious diseases on Blackwell's Island, Health Commissioner Janeway, with Assistant Sanitary Superintendent James and Dr. Taylor of the vaccinating corps, recently made a trip to North Brother's Island, with a view to securing a site for a new pavilion hospital for contagious diseases. This island is considered eminently suited for the purpose, and there is already a pavilion on it which was formerly used as a small-pox hospital for Queen's County. If immediate possession of the pavilion already on it can be obtained it will be used for the reception of scarlet-fever patients.

A suit for \$10,000 damages, for the loss of an eye, against Dr. Henry D. Noyes, professor of ophthalmology and otology in Bellevue Hospital Medical College, has recently been ended with a disagreement of the jury, ten being in favor of the defendant and two for the plaintiff. The patient came from Massachusetts to the New York Eye and Ear Infirmary, where Dr. Noyes has given his services gratuitously for many years. Cataract was found in both eyes, and it was recommended that both eyes should be operated upon. The patient and his mother, father, and sister testified upon the trial that they objected to any operation upon the left eye, and that the operation was performed without their permission. Dr. Noyes testified that objection was first made, but that afterwards he understood from them that he had authority to operate upon that eye. After the right eye had been operated upon he became satisfied that it would do but little good, while in the left eye there was every prospect of a very successful result. The patient was not seen for two days, and it was then found that dangerous inflammation had set in. The

sight of the right eye, however, had been measurably restored. Some time afterward Dr. Noyes had offered to perform another operation on the left eye, but had not been permitted to do so. During the course of the trial Drs. Loring, Roosa, and Grenning testified as to the skillfulness of Dr. Noyes's treatment of the plaintiff's eyes.

— The Physiological School for Weak-Minded and Weak-Bodied Children, which was established in New York by the late Dr. Edward Seguin, is to be continued by Mrs. Seguin, who has for a long time been associated with him in his educational work. It is the aim of this institution to develop the functions by the exercise of the organs, and to train the organs in view of improving their functions. Shortly before his death, Dr. Seguin spoke of the plan of training adopted in this school as follows: "Thus, in the youngest children the retrograde effects of isolation are at once prevented by an early drill of their activity. In children of an age to go to school the functions of relation are regulated and intellectualized. In the older ones the prevalent, though often hidden, aptitude is studied and trained, in order to prepare a redeeming capacity, be it ever so small, for some useful occupation. This application of physiology to education was the work of my youth, and has been the main object of my thoughts for forty-two years. I give it my last years, with the assistance of my wife, meaning to leave her the young and clear-headed exponent of the method I have scattered, but not exhausted, in many books, pamphlets, and living lessons."

— In view of the extraordinary number of emigrants and others arriving at the port of New York during the past year, constant vigilance was required to prevent the introduction of contagious diseases, as the Governor of the State informs the public in his annual message.

Nine hundred and sixty-eight vessels arrived from ports subject to yellow fever, and two hundred and ninety-one from ports actually infected. Of these, one hundred and thirty-seven vessels reported sickness at the port of departure or on the passage. Ninety-eight cases of fever were admitted to the quarantine hospital during the season, of which twenty-seven were yellow fever. Of the latter number, ten died; and of all other cases seven proved fatal, and eighty-one recovered. So far as is known no case of infectious or contagious disease has passed the quarantine.

The quarantine establishment, as the Governor informs us, has been visited during the past year by a number of eminent professional representatives of the health departments of other States and countries, who expressed their unqualified approval of its condition and management, and acknowledged the belief that the New York quarantine was superior to any other.

WASHINGTON.

— The International Sanitary Conference is now holding private sessions at the State Department; its progress is slow and diplomatic, and its proceedings will probably not be given to the public for some

time to come, the questions brought before it being of a nature to require further instructions on the part of some of the delegates from their home governments. Its members comprise the following: the English and German consuls-general at New York; the French, Spanish, Russian, Turkish, Japanese, Sweden, and Norway, Portuguese, Chilean, and Netherlands, ministers resident; Belgium, Italy, and Denmark by their *chargé d'affaires*; China by the assistant minister; Mexico by Don Manuel M. de Zamacoa; Austria by Count Bethel; Spain and Portugal have each sent a specialist in addition to their diplomatic representation; Canada is represented by Dr. Tache, deputy minister of agriculture, and the United States by Drs. Cabell and Turner, as president and secretary of the National Board of Health; assistant secretary of state Hay being our diplomatic representative.

ST. LOUIS.

— A short time ago there was so much talk about a prevalence of diphtheria in the city that several of the daily papers investigated the matter, and their statements that there were only a very few cases, and that there had only been a few deaths from this cause, were, in the main, correct.

Dr. J. M. Scott, a practitioner of long standing and prominent in the profession here, gave your correspondent the points in two interesting cases occurring recently in his practice. The first occurred in a family of three children: two of them had scarlatina; the third did not have scarlatina, but was taken ill with diphtheria, and died. This case was reported to the St. Louis Medical Society, and excited considerable discussion on the question of the identity of the two diseases. In the second case the circumstances were similar. Two (or three) children in a family had scarlatina; the other remaining child had diphtheria, from which it is at the present time convalescent. In the latter case the treatment was one-fourth-grain doses of calomel and five grains of soda bicarbonate every two hours.

Dr. J. S. B. Alleyne, professor of materia medica, St. Louis Medical College, related to your correspondent the following case: Scarlatina had run through a whole family of children; the last child taking it had a mild attack, but this was followed by diphtheria, from which the patient died. He considered it a well-marked case of diphtheria. None of the other children had diphtheria. The leading practitioners of the city, particularly those practicing chiefly among children, the physicians in the employment of the city, all report a few cases of diphtheria; quite a number of cases of scarlatina, some of these latter cases having severe throat complications; and a large number of cases of what is called follicular pharyngitis.

There are here, as there are everywhere else, a large number of practitioners of one kind and another who are fond of calling every bad case of sore throat they see diphtheria or a diphtheritic inflammation. It is their worthless statements that have caused some unnecessary apprehensions among the people of St. Louis on this score.

Miscellany.

LETTER FROM VIENNA.

MR. EDITOR, — Antiseptic surgery, as practiced at present in Professor Billroth's clinic, is not the least successful among the various attempts which have been made at simplifying Lister's method. The General Hospital of Vienna, situated in a thickly populated part of a large city, and containing three thousand beds, seven hundred of which are occupied by surgical patients, probably offers a more extended field for "Listerism" than any other hospital in the world. The inconveniences as well as the great advantages of employing Lister's method in such a place are keenly felt, and in Billroth's clinic the most inconvenient and disagreeable part of the whole Listerian apparatus — the spray — is now replaced by simple irrigation with an antiseptic solution.

The theoretical grounds for this proceeding are set forth by Dr. Miculicz, assistant in the clinic, in an article in Von Langenbeck's *Archiv*.¹ Dr. Miculicz believes that the air is the least dangerous of all sources of infection to which wounds are exposed. A liter of the air of an ordinary operating theatre has been found to contain ten germs, which, in a room which contains two thousand meters of air, would give a total of twenty million germs. Five times this number, however, are contained in a single drop of decomposing fluid; so that, as the author puts it, there may be more germs under one of the operator's finger-nails, or on the points of a single pair of forceps, than in all the air in the room. The atmospheric germs, moreover, are nearly all dry, and experiments show that dry germs are far more inert than moist ones, which are introduced into wounds by direct contact. It follows, then, that both in respect to the quantity and quality of its germs, the air is a comparatively insignificant source of infection. But as it is not so insignificant that its effects may be safely disregarded in a large hospital, and as the purpose of the spray is to guard against dangers from this source, Dr. Miculicz raises the question whether this purpose is as well answered by the spray as by irrigation. He finds, by a carefully conducted series of experiments, that the mechanical effect of the spray is to carry along with it and leave in the wound at least four times as many germs as would find their way there under ordinary circumstances. To the statement that this is unimportant if the germs are all destroyed by the spray the experimenter replies that, as the concentration of the spray varies greatly with the amount of pressure by which the spray is produced, the distance of the spray-producer from the wound, and the formation of the nozzle, it is difficult to tell whether the spray is always strong enough to destroy the germs which it throws into the wound. The chemical action of the spray is found to be nothing more than to render the surface of the wound slightly antiseptic. While in the air, the contact of the vapor with the germs is not of sufficiently long duration to destroy them.

In favor of irrigation, it is claimed that no extra germs are thrown into the wound; that all germs which inevitably fall in are washed away, instead of being allowed to stay; that, as the strength of the solution is always known, the operator can be sure that the wound is thoroughly disinfected, and that the patient is not chilled by being kept in a cool vapor bath during a

¹ Archiv f. klinische Chirurgie, Bd. xxv., p. 707.

long operation. In short, it is claimed that irrigation possesses positive advantages over spray without sharing its defects. The only practical disadvantage of irrigation is that the subsequent discharge from the wound is apt to be greater than when spray is employed. A more frequent change of dressing is thus necessitated, but Dr. Mienliez considers this a very slight disadvantage when the greater certainty of antiseptis afforded by irrigation is considered.

The antiseptic method, as practiced by Billroth, is as follows: Before beginning an operation, the part to be operated on is shaved, then scrubbed with soap and water, and finally washed with carbolic-acid solution. If the skin seems greasy it is washed with ether. The nail-brush and the carbolic solution are used in the same way on the hands of the operator and all the assistants, and everybody who is employed in the amphitheatre wears a long clean linen duster. All the instruments, ligatures, sutures, and needles lie in carbolic solution during the operation, while sponges and drainage tubes are always kept carbolized. A small tank against the wall contains the irrigating fluid, a three per cent. solution of carbolic acid, which is brought within reach of the operator by a rubber tube, whose nozzle is furnished with a stop-cock, by which the force of the stream is regulated. If the operation is a small or superficial one, irrigation is employed only at the close, just before sewing up, when the wound is washed out with great care; but the process is repeated a number of times during the operation if a deep hole is made. After the introduction of the drainage tube the wound is sewed up, a piece of gutta-percha paper laid over it, and a very large quantity of Lister's gauze applied. The innermost layers of the gauze are the only ones which are soaked in the carbolic solution, and they are not applied smoothly, but crumpled up and laid on loosely. The outer layers of the gauze are folded smoothly and put on dry, the mackintosh protective occupies its ordinary place, and the whole dressing is firmly held in position by a gauze bandage.

It will thus be seen that in guarding against infection the most scrupulous attention is paid to every detail. In changing a dressing, the same care is observed, the irrigator, of course, still taking the place of the spray. One point which deserves special notice is with reference to sponges. The sponge is regarded as one of the most dangerous sources of infection, and is never used except in the operating theatre, and there only on a freshly made wound. In doing ovariectomy, Billroth uses no sponges which have not been soaked at least fifteen days in a five per cent. solution of carbolic, as he has found living bacteria in sponges which have been kept twelve days in such a solution. In changing dressings and in wiping all wounds which discharge anything beside fresh blood, small "wads" of cotton batting, which are always soaking in carbolic solution and which are thrown away as soon as used, do the work of sponges. If, by any chance, a sponge has come in contact with pus, it is never used again.

In securing first intention, great importance is attached to compression of the wound and immobility of the part. The dressing is carefully adjusted and the bandage applied so as to afford a very firm and equable pressure. In wounds of any size, deep sutures are used, which are fastened with lead disks and pierced bullets. If the seam is a long one, the disks are replaced by two strips of lead placed one on each side of the seam and parallel with it. Immobility is secured by a

bandage of coarse muslin impregnated with starch and dextrine. The ordinary use to which this material is put is the stiffening of ladies' dresses, and it can be had at any dressmaker's. For surgical purposes it is made up into rollers, which are soaked in water and applied outside of everything else. The bandage stiffens in a few minutes, and although, of course, not so solid as plaster of Paris, it offers very effectual resistance to any ordinary movement on the part of the patient. It is especially useful in operations on the neck, such numbers of which are performed by Billroth. After one of these operations, the patient's head, neck, and chest are enveloped in this bandage, which renders motion of the head impossible. The bandage must be cut or soaked in warm water in order to remove it, but there is said to be no trouble in cutting it with a stout pair of shears.

It is now ten months since the use of the spray has been abandoned in Billroth's clinic. The experiment has proved in the highest degree satisfactory. Operations are even more successful than when performed under spray, and a troublesome piece of apparatus is dispensed with. The laparotomies which have been performed without spray show in a striking manner what results can be obtained by this method of operation. Since September Billroth has done laparotomy eleven times. Two of these operations were hysterotomies, one per vaginam, the other through the abdominal walls. The remaining nine were ovariectomies. These operations were all performed in the General Hospital, without spray or irrigation, and recovery in every case was perfect.

Litholapaxy is attracting a good deal of attention in Vienna, and has been performed six times by Billroth. The operation lasted, in the different cases, from fifteen minutes to two hours, and the calculi varied in diameter from one and a half to four centimeters. All the operations were successful, and the subsequent febrile reaction insignificant. In only one case, that of the two hours' sitting, was the operation followed by a chill.

A death under chloroform occurred in Billroth's operating theatre a short time ago, during an attempt to reduce a hip dislocation, the result of chronic hip disease. The patient was a boy fourteen years old. The anæsthetic used was a mixture of one hundred parts of chloroform, thirty of ether, and thirty of alcohol. This is the first death which has occurred from the administration of this mixture, which has been in constant use here for ten years. JOHN B. WHEELER, M. D.

VIENNA, December 26, 1880.

GROSS SURGICAL PRIZE.

THE Philadelphia Academy of Surgery offers through its president, Professor S. D. Gross, a prize of five hundred dollars for the best essay on the Surgical Pathology and Treatment of Tumors, or Morbid Growths of the Testis, Scrotum, and Spermatie Cord, to be open exclusively to American surgeons.

(1.) The essay must be founded solely upon original investigations, be illustrated by suitable drawings, microscopical and other, and be written in scholarly English.

(2.) The essay shall be the property of the academy, which shall, at its option, permit the author to publish it at his own risk or expense.

(3.) Each essay must be accompanied by a motto, and by a sealed letter containing the author's name.

(4.) The essay must comprise an amount of matter equal to two hundred and fifty pages octavo.

(5.) The award will be made at the meeting of the academy in January, 1884, by a committee of five of its Fellows.

The committee, which has been appointed, consists of D. Hayes Agnew, M. D.; William Hunt, M. D.; R. J. Levis, M. D.; J. H. Packard, M. D.; J. Ewing Mears, M. D.

All essays should be forwarded to the secretary of the committee, at a date not later than October 15, 1883, J. Ewing Mears, M. D., secretary of the committee, 1429 Walnut Street, Philadelphia, Pa.

FEES OF DOCTORS.

THE signal defeat of a bill — it was smothered in committee — introduced at the last session of the Kentucky legislature, to place the fees of doctors on the list of preferred claims now allowed by the statute,

causes the *Louisville Medical News* to invite communications upon the thesis, What will increase the Material Prosperity of Doctors? The discussion of the theme will of course involve the consideration of many subsidiary points. Prominent among these will be the vastness of the army which has to divide the rations of medicine. How are we to get rid of the overplus by other method than the slow process of starving? How are we to prevent ambitious schools from crowding the ranks beyond the power of pestilence to thin? Which promises to be the most successful bar against admission, — an educational, pecuniary, or legal standard? And the army being formed, does it fight in proper lines and under proper regulations? Are the officers to be trusted? Are they, or are they not, satisfied with getting the choicest spoils, and do they not exact discipline for selfish ends? Is, or is not, the code a humbug, — a mighty tower for the strong and a snare for the weak? Or, dropping the military and coming down to ordinary life, would, or would not, medicine be benefited in dignity as well as in worldly goods by putting it on a mere commercial basis? It is easier to suggest than to make reply.

Deaths reported 2588; 1024 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 586, consumption 390, lung diseases 339, diphtheria and

croup 282, scarlet fever 108, small-pox 62, typhoid fever 31, diarrhoeal diseases 24, erysipelas 19, malarial fevers 18, measles 16, cerebro-spinal meningitis 11, whooping-cough 10, puerperal fever five. From *typhoid fever*, Philadelphia six, Boston five,

St. Louis and Providence three, Baltimore and Pittsburgh two, New York, Brooklyn, Cincinnati, District of Columbia, Lowell, Fall River, Lawrence, Springfield, Woburn, and Plymouth one. From *diarrheal diseases*, St. Louis six, New York five, Baltimore, Boston, and New Haven two, Brooklyn, Cincinnati, District of Columbia, Pittsburgh, Providence, Nashville, and Somerville one. From *erysipelas*, New York five, St. Louis four, Philadelphia three, Baltimore, Cincinnati, Buffalo, New Haven, Holyoke, Chelsea, and Newburyport one. From *malarial fevers*, New York five, Brooklyn and St. Louis four, Baltimore two, Boston, Pittsburgh, and Buffalo one. From *measles*, Boston seven, Brooklyn three, New York two, Baltimore, District of Columbia, Milwaukee, and Lowell one. From *cerebro-spinal meningitis*, New York five, Philadelphia and St. Louis two, Lawrence and Holyoke one. From *whooping-cough*, Cincinnati two, Philadelphia, St. Louis, Baltimore, Boston, Pittsburgh, Cambridge, Salem, and Waltham one. From *puerperal fever*, Cincinnati two, St. Louis, Fall River, and Lynn one.

One hundred and thirty cases of diphtheria, 113 of scarlet fever, 14 of measles, and two of small-pox were reported in Brooklyn; diphtheria 49, scarlet fever 17, in Boston; scarlet fever 41, diphtheria 11, in Milwaukee.

In 38 cities and towns of Massachusetts, with a population of 1,066,615 (population of the State 1,783,086), the total death rate for the week was 21.31, against 21.21 and 20.86 for the previous two weeks.

For the week ending December 18th, in 149 German cities and towns, with an estimated population of 7,708,627, the death-

rate was 22.5. Deaths reported 3334; 1540 under five: pulmonary consumption 451, acute diseases of the respiratory organs 302, diphtheria and croup 166, scarlet fever 83, typhoid fever 79, whooping-cough 56, measles and röteln 54, puerperal fever 17, small-pox (Königsberg two, Thorn, Wesel) four, typhus fever (Berlin) one. The death-rates ranged from 7.2 in Potsdam to 38.9 in Aachen; Königsberg 23; Breslau 23.4; Manich 23.8; Dresden 21.2; Berlin 21.4; Leipzig 15.9; Hamburg 27.8; Hanover 17.7; Bremen 19.1; Cologne 28.5; Frankfurt 13.6; Strasbourg 22.6.

For the week ending December 25th, in the 20 English cities, with an estimated population of 7,499,468, the death-rate was 23.7. Deaths reported 3408: acute diseases of the respiratory organs 353, scarlet fever 137, measles 84, whooping-cough 72, fever 48, diarrhoea 23, diphtheria 17, small-pox (London) 17. The death-rates ranged from 16 in Newcastle-upon-Tyne and Portsmouth to 30 in Wolverhampton, Liverpool, and Nottingham; Sheffield 19; Birmingham 21; Bristol and London 23; Manchester 24; Leeds 26. In Edinburgh 20; Glasgow 23; Dublin 36.

In the 20 chief towns in Switzerland for the week ending December 25th, estimated population 522,856, there were 23 deaths from acute diseases of the respiratory organs, diphtheria and croup 13, typhoid fever five, small-pox five, diarrheal diseases five, puerperal fever one.

NOTE. The returns from the new Swiss census not being ready, the populations and death-rates are not given.

The meteorological record for the week in Boston was as follows:—

JOHN HUNTER AND HIS PUPILS.¹

ABSTRACT OF AN ADDRESS DELIVERED BEFORE THE
ACADEMY OF SURGERY, PHILADELPHIA, JANUARY
12, 1881.

BY PROFESSOR S. D. GROSS.

LIFE, CHARACTER, AND SERVICES OF JOHN HUNTER.

ALL intelligent readers of biography are more or less familiar with the labors and writings of John Hunter, his marvelous genius, and his vast contributions to science. In the medical profession his name is, and always will be, a household word throughout the civilized world; it is spoken with respect and reverence in every college amphitheatre, and is deeply engraved upon the mind of every student of surgery. Nevertheless there are, it may safely be asserted, many points of interest in his life, and many traits of character which have escaped our memory, or which have never been so thoroughly impressed upon our attention as to enable us to appreciate them at their full value.

With the exception of Hippocrates, the father of medicine, John Hunter is the grandest figure in the history of our profession. I make no exception in favor of Ambrose Paré, the father of French surgery and the inventor of the ligature for the arrest of hæmorrhage, a contrivance which has been instrumental in saving so many lives; of Albert von Haller, the father of scientific physiology; or even of Xavier Bichat, the founder of general anatomy, and one of the most remarkable men that have ever lived. Shall we make an exception in favor of William Harvey? No; I will not exclude from this list even the immortal discoverer of the circulation of the blood. Great as these men were, and vast as are the blessings which they have conferred upon their race, it is no disparagement to them to say that John Hunter was, in many respects, their superior: not in learning, for herein Haller had greatly the advantage; not in the amount of suffering which he has been instrumental in relieving by his surgical writings, for in this respect Ambrose Paré was fully his equal; not even in inventive genius, for here it will be found that Bichat, who created a new science before he was thirty years of age, was not a whit his inferior. While Hunter had many traits of character in common with these and other great men, he possessed some features that were peculiarly his own. He was not only a great surgeon, a wise physician, and a great anatomist and physiologist, human and comparative, but, above all, he was a philosopher whose mental grasp embraced the whole range of nature's works, from the most humble structure to the most complex and the most lofty. He was emphatically the Newton of the medical profession, and what Pope said of that great philosopher may, by paraphrase, be said with equal force and truth of Hunter:—

"Nature and Nature's law lay hid in night;
God said, 'Let Hunter be,' and all was light."

Hunter is peerless in the history of British surgery; and after the lapse of nearly a century the profession turns to his memory with increased reverence for his transcendent genius, his matchless ability, and his un-

equaled services. To say that he was simply the founder of scientific surgery would fall far short of his great deserts; to do him full justice we must add that he was the father also of scientific zoology and of comparative physiology.

To appreciate Hunter's character fully, or, in other words, to form a just idea of his merits as an observer, an experimenter, an investigator, a teacher, an author, and a man of genius, it will be necessary to take, as it were, a bird's-eye view of the history of surgery at the time he appeared upon the active stage of life; how he came to study medicine, who were his teachers and contemporaries, and what influence he exerted by his discoveries and improvements upon his age and upon future generations.

Of the boyhood of Hunter very little is known, and that little is not particularly creditable to him. He was the youngest of ten children, and was born at Long Calderwood, Lanarkshire, Scotland, on the 14th of February, 1728.² His father, who was nearly seventy years old at the time of his birth, was descended from an old family in Ayrshire, and cultivated a small landed estate, which afforded him but a scanty subsistence. That he was a man of refinement and of some education, added to a high moral and religious sense, is proved by several letters, copies of which are still extant. His mother was the daughter of the treasurer of Glasgow. At the age of ten John was left an orphan, in the sole care of his mother, who, although a woman of strong mind, failed to exercise much influence over him. At the age of seventeen, or thereabout, learning that his brother-in-law, a cabinet-maker at Glasgow, married to a sister whom he dearly loved, was laboring under pecuniary embarrassment, he paid him a visit, and for a time assisted him in his business, not as an apprentice, but a volunteer, working probably at small wages, or simply for his board and clothing. It was this circumstance which induced some of his envious contemporaries to assert that in early life he had been a wheelwright or a carpenter,—a statement for which there is not the slightest foundation in truth. Tiring of an occupation which, it may be presumed, had nothing genial in it, and hearing that his brother, Dr. William Hunter, who had been living for some time in London, was doing a large and lucrative practice, and rapidly growing in reputation, a desire seized him to visit what must have appeared to his heated fancy as a sort of Eldorado. The meeting between the two brothers was cordial, and arrangements were at once effected by which John became an assistant in William's anatomical rooms, which, although only recently opened, had already acquired marked celebrity on account of their educational advantages. It was there that young Hunter first became aware of his latent powers, and threw off the incubus which had so long oppressed his soul. A new life broke in upon him; his ambition was aroused; industry, steady and unremitting, took the place of idleness, and the undecided, wavering, erring youth, stimulated by the new atmosphere in which he was now daily immersed, assumed the attitude and the assured character of the philosopher and the student of nature. Who or what brought about these wonderful changes in the life and conduct of this young man, so sudden, so unexpected? It is not difficult to answer the question. It was simply William Hunter, and the influence of his example. John saw the wonder-

¹ This address is to be published in full by Presley Blakiston, of Philadelphia, in book form, making a small octavo of over one hundred pages. It will have a handsome portrait of John Hunter as a frontispiece.

² The parish register gives the 13th of February, but the College of Surgeons always celebrates the 14th as Hunter's birthday. Sir Everard Home in his Life gives the 14th of July as the proper date.

ful things which his brother was doing in building up a great anatomical museum, and it is therefore not surprising that his tastes should soon have taken a similar direction. However this may be, his proficiency as a practical anatomist was so very rapid that before the end of twelve months he was intrusted with the preparation of his brother's subjects for his anatomical lectures; and in 1755, seven years after his arrival in London, he was admitted to a partnership in his private school.¹ Long before this time he had acquired great reputation among his classmates as an expert dissector and an excellent anatomist. He had now become an active, industrious worker, thoroughly in love with his occupation. The summer of 1749 was spent by him at Chelsea Hospital, under the instruction of the celebrated Cheselden, who was then nearing his grave; and in 1751 he became a pupil at St. Bartholomew's Hospital, where he availed himself of the teachings of the not less renowned Percivall Pott, another great luminary of British surgery. It has been stated that Hunter's early education was sadly neglected. Whether it was that he was himself painfully conscious of the fact, or, what is much more probable, because his friends urged him to take the step, he entered, in 1753, as a gentleman commoner at St. Mary's Hall, Oxford. His brother William was very anxious that he should abandon surgery and study medicine, which was at that time regarded, and, perhaps, not without reason in the then existing state of the science, as a higher branch of the healing art. With this end in view it was deemed very desirable that John should have a respectable knowledge of Greek and Latin, as no physician was considered as being properly educated without it. The effort, however, proved abortive. Hunter was now twenty-five years of age, and he had no disposition to shut himself up within the narrow walls of a college, or to give up the idea, formed soon after he settled in London, of becoming a great surgeon. He looked upon such studies as a waste of time, and in referring to the subject, some years afterwards, he thus feelingly expressed himself: "They wanted," he said, "to make an old woman of me, or that I should stuff Latin and Greek at the University; but," added he, significantly pressing his thumb-nail on the table, "these schemes I cracked like so many vermin as they came before me."² One cannot but regret that Hunter did not carry out the wishes of his friends. A little "stuffing" of Latin and Greek would have been of vast benefit to him in preventing those errors of style and of literary composition which so greatly disfigure and obscure his writings.

In 1751 Hunter became a pupil at St. George's Hospital, where two years later he received the appointment of house-surgeon. This position he retained, however, only for a short time; for, owing to his incessant labors, his health was beginning to suffer, and fears were entertained that he was threatened with phthisis. This compelled him to seek safety in change of air and scene. Through the agency of his friends he was made a staff-surgeon, and was at once sent with the army to Belle Isle, an island off the western coast of France, where he enjoyed ample opportunities

for the study of diseases and accidents, and gathered materials for the composition of his work on gunshot wounds. These opportunities were further enhanced the following year during the war in the Peninsula. On the restoration of peace in 1763, Hunter returned to London, invigorated in health, and loaded with new knowledge, but poor in pocket, having saved little, if anything, of his pay as a military surgeon. His struggles as a young practitioner in the great metropolis were long, arduous, and disheartening. The few connections which he had formed before he joined the army were lost to him, and his place in his brother's dissecting-rooms and amphitheatre was occupied by Mr. Hewson, a young but rising anatomist, afterwards so celebrated for his discoveries in the lymphatic vessels. He had, therefore, now nothing to depend upon but his half pay and his own indomitable will, stimulated by his necessities and by his lofty ambition. Like many a young man destined to attain to eminence, he literally carried his fortune in his own hands. Although full of energy, he was not a man to make friends or to inspire public confidence rapidly. His manners were abrupt, and, at times, even coarse and repulsive. He possessed none of those arts which so easily please and fascinate people, and which so often do more in securing respect and business than the highest talent or the most consummate knowledge. The truth is he had too good an opinion of himself, and too little respect for that of his professional brethren. He felt conscious of his superior mental endowments, and therefore looked upon the world around him with a species of contempt, which seldom fails to recoil with interest upon its author. The humble Scotch youth, by his intercourse with army surgeons and gay society, was doubtless led to form a very humble estimate of the profession generally. Besides, the field upon which he had now entered was occupied by able men. Pott stood deservedly at the head of the profession; Hawkins, Bromfield, Sharp, and Warner also enjoyed a large practice; and there were a number of younger surgeons who were rapidly rising in public estimation. In order to increase his income, as well as to afford himself useful occupation, Hunter now opened a school of anatomy and operative surgery, and delivered regular courses of lectures. He also took private pupils, each of whom was apprenticed to him for five years, at a fee of five hundred guineas, a sum equivalent to about \$2650 of our money; but after all not so large when it is recollected that it included board and lodging. This practice of taking private pupils was continued until within a short time of Mr. Hunter's death. Among the list of the young men who enjoyed this privilege were, not to mention others, Edward Jenner, Abernethy, Physick, and John Thomson, the author of the celebrated treatise on inflammation.

In 1767 Hunter was elected a member of the Corporation of Surgeons, an institution which in 1800 was merged into the Royal College of Surgeons. Although the Corporation embraced some excellent men, Hunter had so little respect for it that he seldom attended its meetings or took any active part in its deliberations. Good anatomist and experienced surgeon as he had long been known to be, it was not until he was forty years of age that he received a hospital appointment. In 1768 a vacancy occurred in St. George's Hospital, to which, through the influence mainly of his brother, Dr. William Hunter, he was

¹ The first task assigned to him was the dissection of the muscles of an arm, which was so well and so rapidly done that he was next set to preparing an arm with the blood-vessels. This labor was also performed in so satisfactory a manner as to elicit the highest commendation from his brother, who predicted his future greatness as an anatomist, and told him "he should never want employment."

² Oltley's Life of John Hunter, Palmer's edition, vol. i. p. 14. London, 1837.

elected by a large majority over his competitors. This position, one always eagerly sought by young men, gave him a new start, and his practice immediately increased in consequence. Indeed, his fortune as a surgeon was now fully assured. He no longer lacked patients, and the rigid economy which he had been obliged to exercise in his daily outlays gave way to comparative affluence. He now bought a lot of ground at a place called Earl's Court, about two miles from London, and erected a large and commodious house, still famous as his former residence. In 1771, at the age of forty-three, he married Ann, the daughter of a surgeon in General Burgoyne's Light Horse, and a sister of Mr., afterwards Sir Everard, Home, whose ultimate career is so intimately connected with that of Hunter. Miss Home was a lady of varied accomplishments, elegant manners, fine æsthetic taste, a good musician, fond of society, and somewhat of a blue-stocking.

The house at Earl's Court was erected for the express purpose of accommodating his preparations, which already amounted to a cumbersome collection; but it also served as a summer residence for the family. On the spacious grounds now at his command he gathered a large number of animals, birds, fishes, and reptiles, as well as various other objects of natural history; and one of his favorite amusements in the summer and autumn, after the labors of the day were over, was to ramble among these creatures, in familiar intercourse, petting and talking with some, and preserving friendly relations with all. It was at Earl's Court that Hunter entered upon that career which invested his life with so much *éclat*, and established for him that fame which made him one of the most renowned men of his age. His house in town, which had hitherto been a sort of curiosity shop, he still retained. He also continued his lectures on anatomy and surgery, took pupils, as formerly, into his house, as was then the custom all over England, and spent all the time he could snatch from his practice in the study of comparative anatomy and natural history and in making preparations for his museum. His habit was to rise at four o'clock in the morning, to spend from four to five hours in his dissecting-rooms, and then to step into his carriage to make his daily rounds among his patients. He had no fondness for surgical practice or consultations, and attended to business only because it afforded him the means of purchasing objects of curiosity or of natural history, saying, as he laid aside his scalpel and forceps, "Well, Lynn," a pupil and an intimate friend, "I must go, and earn that d—d guinea, or I shall be sure to want it to-morrow." It is obvious enough that a man with such feelings could not have much love for the drudgery of his profession. Whatever interfered with his studies and his philosophical contemplations was regarded by him as a serious interruption. He was lavish in his expenditures, and was often obliged to borrow money to meet his obligations. Whenever he had accumulated ten guineas from his earnings, he invariably appropriated a part to the purchase of material for his museum. Every available source was laid under contribution for specimens of animals, birds, fishes, reptiles, and insects,—the Zoölogical Garden, then in the Tower, traveling menageries, sea-captains sailing to different countries, and persons at home or abroad. With his friend and pupil, Dr. Edward Jenner, the discoverer of vaccination, he carried on a life-long correspondence respecting material of this kind, and the habits of birds, bees, rep-

tiles, and fishes. In one of his letters he asks, "Have you large trees of different kinds that you can make free with? If you have, I will put you upon a set of experiments with regard to the heat of vegetables." He asks a similar question with regard to bats, the hedgehog, and other animals. Indeed, he must have kept Jenner often very busy, for nothing short of thorough work answered Hunter's purpose. He took nothing on credit. In one of his letters to Jenner he asks for information about the temperature of the hedgehog. He observes, "I think your solution is just; but why think? Why not try the experiment?" and then adds, "Try the heat; cut off a leg at the same place; cut off the head, and expose the heart, and let me know the result of the whole." The temperature of insects, animals, and vegetables occupied much of Hunter's thoughts, and he eventually published a valuable paper upon the subject in the *Philosophical Transactions*. In 1767 he was elected a Fellow of the Royal Society; and in the following year he sent to that body a memoir on the means to be employed in the resuscitation of drowned persons. In 1776 he was appointed Croonian lecturer by the Royal Society, and the subject which he selected for discussion was muscular motion, into which, as usual, he introduced much novel and interesting matter. The course was completed in 1782, and the society asked for a copy of it for publication; but to this demand Hunter demurred, on the ground that he had not completed his investigations. Much of the matter, however, found its way afterwards into some of his various writings, so that, probably, nothing of value has been lost.

We must next inquire into Hunter's merits as an author. Notwithstanding his want of scholarship and the labor with which he composed, he was a prolific writer. Many of his contributions, especially those on comparative anatomy and physiology, found their way into the *Transactions of the Royal Society* and other publications, in which they generally elicited much attention. His first systematic work was his *Treatise on the Natural History and Diseases of the Human Teeth*, the first part of which was issued in 1771, and the second seven years later. The work was well received, and greatly enhanced his reputation as an acute observer and investigator. His attention seems to have been originally directed to the subject by the deplorable state of dentistry, which was almost solely confined to the barber or ignorant mechanic, whose chief occupation consisted in extracting and plugging teeth. Although vast improvements have been effected since the time in which he wrote,—improvements which far exceed those of any other specialty in surgery, save that of the eye,—to Hunter is justly due the great merit of rescuing dentistry from the hands of empiricism, and of placing it upon a broad and scientific basis by pointing out, in distinct terms, the physiological and pathological relations which the teeth bear to the rest of the system. It is in this work that we find the first notice of the operation of transplanting teeth from the mouth of one person into that of another,—an operation first practiced by Hunter, and frequently repeated under his supervision, until, owing to the serious consequences which so often attended it, it was finally abandoned. It was ascertained that, although the transplanted tooth, in many cases, readily contracted adhesions and even vascular connections with the gums, it either soon dropped out, or caused so much irritation as to require its removal. Occasionally, in-

deed, the operation was followed by syphilis, as when a tooth was transplanted from a tainted to a healthy person. We may imagine how delighted Hunter must have been when he found that he could transplant a human tooth to the comb of a cock, or the testicle of a cock to the abdomen of a hen,—operations which, in several instances, he performed most successfully.

The *Treatise on the Venereal Disease* appeared in 1776, followed by a second edition in 1778. Having been long and impatiently expected, it at once attracted general attention. Although extraordinary care had been bestowed upon its preparation, it abounded in blemishes, for the correction of which the author availed himself of the services of a committee of three of his most learned and accomplished friends. His account of venereal affections was for upwards of a third of a century the best authority on the subject in any language, and his description of the indurated chancre is so graphic and distinct that it will always be called by his name. True, it had been recognized by previous observers, as Torella, De Vigo, Fallopius, and Ambrose Paré, but no one had ever so clearly delineated its distinctive features.

The *Treatise on the Blood, Inflammation, and Gun-shot Wounds*, a work of vast labor and the most patient research, and upon which Hunter's fame as a surgeon and a medical philosopher largely rests, was published, in 1794, under the supervision of Dr. Matthew Baillie and Sir Everard Home, only about one third of the proofs having been revised by the author at the time of his death. Notwithstanding Hunter strove to render the work as perfect as possible, it was obscured by numerous errors of style, and the punctuation was execrable. A *Life*, by Sir Everard Home, is prefixed to the volume, but this, for some reason or other, was omitted in the succeeding editions of 1812, 1818, and 1828. These editions were, it would seem, simply reprints of the first, with all the original errors.

His work on the *Animal Economy*, consisting mainly of a series of papers considerably altered in matter as well as style, and previously printed in the *Philosophical Transactions*, was published in 1786. The articles relate chiefly to anatomical and physiological subjects, and evince that rare spirit of generalization and mental acumen so characteristic of Hunter.

One reason, apparently, why Hunter's lectures and writings were marked by such glaring obscurities was that he was obliged to invent so many new expressions in order to meet the wants created by his own labors and discoveries. He was the first, for instance, to use such expressions as "adhesive inflammation," "ulcerative absorption," "morbid poisons," and others of a similar kind, unknown to his contemporaries, who felt little inclination to acquaint themselves with their import. Hunter never verified Bacon's maxim that "writing makes an exact man." His style seems to have been little, if any, better in his later than it was in his earlier years, when, as a raw student, he entered upon his gigantic work. There are men who never speak or write grammatically; they cannot overcome the defects of their early education; and of this class of men John Hunter was a remarkable example. His genius soared above the regions of grammar and of rhetoric.¹

¹ In reading the works of Hunter and of Bichat one cannot fail to be struck with the peculiarities of their style; both were slovenly writers, and their language is often so obscured by blemishes as to render it difficult to comprehend its proper meaning. Hunter composed slowly, Bichat rapidly; the latter never revised his MSS., and it is sad that his *General Anatomy*, in four volumes, was written and published in a single year.

He had a high opinion of putting one's thoughts into writing. "It resembles," he said, "a tradesman taking stock, without which he never knows what he possesses or in what he is deficient."

With the exception of an attack of pneumonia in 1759, Hunter enjoyed excellent health during the first forty years of his life. In 1769 he was seized with a severe fit of the gout, which greatly alarmed him, as it was attended with excessive pallor of his countenance, and, for nearly three quarters of an hour, with total extinction of the pulse, and almost entire absence of breathing. Notwithstanding this he soon resumed his labors, which now, however, began seriously to undermine the powers of his constitution, which was still further impaired in 1775 by a spasmodic affliction of different parts of the body, preceded by symptoms of his former complaint. The heart at length became involved, and on one occasion the paroxysm was so violent as to cause syncope. These attacks compelled him for a time to relax his efforts, and to avail himself of the use of the mineral waters of Tunbridge and of Bath. Although his health was greatly benefited by the change, it ever afterward remained in a precarious condition, his cardiac disorders frequently recurring upon the slightest exertion, fatigue, or mental irritation. In December, 1789, four years before his death, he was suddenly seized, while on a visit to a friend, with total loss of memory. He knew not in whose house he was, the name of the street, the object of his call, the name of the family, or, in short, anything he had ever said or done; the machinery of his mind seems to have been almost completely suspended, and a full half hour elapsed before the engine resumed its accustomed work. During all this time, however, consciousness remained, and special sensation was unimpaired. Hunter was so painfully sensible of his situation that he was wont to say to his friends that his life was in the hands of any rascal who chose to fret or worry him. It is therefore not surprising that these attacks should have rendered him nervous and irritable, and less capable of controlling his naturally impetuous temper. His final hour came at last: death, sudden and unexpected, overtook him at St. George's Hospital, at a meeting of the governors and of the surgical staff of that institution, called on business of importance connected with the admission of pupils and the mode of instructing them. During the discussion which ensued Hunter made a remark which one of his colleagues considered it necessary at once flatly to contradict. Choked with angry and tumultuous emotions, Hunter immediately ceased speaking, and, hurrying into an adjoining room, fell, with a deep groan, lifeless into the arms of one of the attending physicians. All attempts to revive him proved abortive. An event so sad and so unusual called forth a wide-spread sympathy, and created a profound sensation wherever his name and fame were known and appreciated. His carriage, drawn by two elegant bay horses, returned soon after without its master, whose body followed in a sedan chair, a sad and appalling spectacle for the family and friends of the great surgeon. Like Caesar, Hunter was murdered by his friends, not in the senate-chamber, but in the consulting-room of a hospital which had so long been the recipient of his services, of which he was the chief ornament, and which should have overlooked his infirmities, some of them inherent in his nature, and others the result of long-continued overwork of mind

and body. An examination of the body revealed the existence of ossification of the mitral valves of the heart and dilatation of the aorta, with thickening of its valves and degeneration of its coats. The coronary arteries were converted into long, rigid tubes. The heart itself was uncommonly small. At the time of his death, on the 16th of October, 1793, Hunter was in his sixty-fifth year. His body was interred in the Church of St. Martin-in-the-Fields, the funeral being strictly private, a few of his medical friends alone being present. His widow was anxious to deposit it in Westminster Abbey, but the fees demanded for admission exceeded her means, and it was not until March 28, 1859, that, through the influence of the medical profession and of public sentiment, it found a final resting-place in that sacred depository of England's illustrious men, of whom he was one of the greatest and most remarkable.¹

For finding the remains of Hunter the profession is solely indebted to the late Mr. Frank Buckland, the well-known naturalist, and a son of a former dean of Westminster Abbey.² He knew that Hunter had been interred in the Church of St. Martin-in-the-Fields, and learning, casually, that it was the intention of the church to reinter the bodies that had been so long confined in its vaults, he took advantage of the opportunity, and after sixteen days of hard work, during which he and his assistant removed three thousand and sixty coffins, and inhaled, much to their detriment, the foul vapors of this horrible necropolis, he at length, when almost in despair, came upon the much-coveted object of his search. The coffin was, in the main, well preserved, and upon a brass plate bore this inscription:—

JOHN HUNTER,
Esq.,
Died 16th Octr.,
1793,
Aged 64 years.

It also represented Hunter's arms,—a hand with an arrow in it, and the three horns of the hunter.

There is not, as has been justly observed by Dean Stanley, a more curious narrative of a chivalrous devotion to the relics of a great man than that displayed in this extraordinary labor of Mr. Buckland, which ended in the triumphant recovery of the remains of the founder of scientific surgery.³

I visited, last summer, the tomb in Westminster Abbey in which the mortal remains of the great man now repose, and found upon the tablet which covers it the subjoined inscription:—

"O Lord, how manifold are thy works."

Beneath
are deposited the remains of
JOHN HUNTER,

Born at Long Calderwood, Lanarkshire, N. B.,

on the 13th of February, 1728,

Died in London on the 16th of October, 1793.

His remains were removed
from the Church of St. Martin-in-the-Fields to this Abbey
on the 28th of March, 1859.

¹ Mrs. Hunter spent her widowhood in a state of retirement, devoting herself to the education of her two children, and to the composition of a small volume of poems, which she published in her latter years, and which is said to have possessed considerable merit as a light effort. She wrote a glowing epitaph in memory of her late husband, intended for a tablet to be placed over his remains; but this was never done, as it was contrary to the rules of St. Martin's Church. She died early in the present century, universally beloved and esteemed.

² *Curiosities of Natural History*, vol. ii. p. 160-179.

³ *Historical Memorials of Westminster Abbey*, page 335. London, 1868.

The Royal College of Surgeons of England has placed this tablet over the grave of Hunter, to record its admiration of his genius as a gifted interpreter of the divine power and wisdom at work in the law of organic life, and its grateful veneration for his services to mankind as the founder of scientific surgery.

In the same year that his remains were interred in the great Abbey, the Royal College of Surgeons adopted measures for the erection of a marble statue to him, and through the efforts mainly of Mr. John F. South, its vice-president, the sum of £1172 was promptly raised for that object. The work was intrusted to Mr. Weekes, the eminent sculptor, who, availing himself of the portrait by Sir Joshua Reynolds and of a cast of Hunter's face taken after death, produced an admirable likeness, a sort of copy in marble, which was completed in 1864, and now graces the museum of the college.

(To be concluded.)

ARE FREE DISPENSARIES ABUSED? ¹

BY J. H. WHITTEMORE, M. D.

Superintendent Massachusetts General Hospital.

THE subject of free dispensaries and the question of their abuse, both in this and foreign countries, had attracted so much attention and consequent discussion, that in 1877 the trustees of the Massachusetts General Hospital requested me to investigate the out-patient department of said hospital, and ascertain, if possible, if a large class of people did not come there for free treatment, who, by reason of their ability to pay for medical services ought not to be allowed this privilege. Sufficient was learned to show that the charity was abused. Since that time the number of patients has steadily and rapidly increased. Inquiry at the Boston Dispensary, and at the Boston City Hospital Dispensary, shows that the same feeling of abuse of their dispensaries exists in the minds of their respective superintendents. With this general feeling existing in the minds of the trustees and superintending officers of the three principal dispensaries of the city, I feel that the subject ought to come before the profession to be discussed, and plans for correction made, if abuses are really believed to exist worthy of notice. To this end I wish to lay before the society certain statistics and facts, perhaps not new, but to refresh your memories, if need be, so that discussion of the subject may be had, and the feeling of the society on this subject may be learned; also to see if any action to correct abuses seems advisable, and if so, what the course to be pursued shall be.

The Boston Dispensary was opened in 1796 "for the purpose of affording medical advice and relief to the sick poor of said town." To July, 1856, there had been treated in this dispensary 118,802 patients. The population of the city of Boston when the dispensary was opened was about 21,000 and had increased in 1856 to about 162,000. In 1860 the number of patients treated in the Boston Dispensary was 16,000. In the Massachusetts General Hospital Out-Patient Department, which had been open fourteen years, the number for 1860 was 4133, making 20,133 the total number treated in the Boston and Massachusetts General Hospital Dispensaries. The population of the

¹ Read before the Boston Society for Medical Improvement and before the Suffolk District Medical Society.

city at this time, 1860, was 177,840, so that there was one free patient to every eight and eight tenths of the population. During the next ten years, to 1870, the number of patients had more than doubled, being in 1870, at the Boston Dispensary, 25,928; at the Massachusetts General Hospital Dispensary, 8767; at the Boston City Hospital Dispensary, — which had been open six years. — 8899; total during the year 1870, 43,594; population of the city, 250,256, — one patient to every five and seven tenths of the population. The last reports of the three above-mentioned dispensaries give the Boston Dispensary 31,618; Massachusetts General Hospital Dispensary 20,566; Boston City Hospital Dispensary 10,309, and in addition to these, I find that during the last year, or in their last reports, the following dispensaries treated patients as follows: Homœopathic Hospital Dispensary 11,826; New England Hospital Dispensary 5212; Charlestown Dispensary 1103, making a total in the six dispensaries of 83,664. Population of the city about 360,000, and one patient to every four and three tenths of the population. In addition to the above dispensaries, Dr. Charles W. Williams in a report to the common council in March last, showed that there were fourteen other free dispensaries and hospitals in the city of Boston.

It has been impossible to get full reports from all of these hospitals and dispensaries. Is it unreasonable to estimate, with above facts, that more than one fourth of all the inhabitants of Boston receive free medical treatment?

The Boston Dispensary, previous to three years ago, admitted all who applied from the city, and furnished them with medicines, the only care taken being to prevent, if possible, non-residents from being treated. Three years since a man was employed to see every person who came for treatment, and an attempt was made to exclude non-residents and undeserving people, especially those, who, on inquiry, did not seem worthy or needing charity; this plan is still kept up with satisfactory results, as the number has fallen from 48,000, in 1877, to 31,618 at their last annual meeting. The superintendent believes that there is still a decided per cent. of those now treated who are unworthy, from their ability to pay for medical services. In June last the dispensary stopped giving medicines and charged ten cents for all prescriptions, except in cases of extreme poverty. Dr. Hastings says the result has been most satisfactory to the financial interests of the dispensary.

In the Massachusetts General Hospital Out-Patient Department, prior to 1877, there were placed in conspicuous places in each room of the department, a box with a card over it, inviting all those liberally inclined, who came there for treatment, to deposit in these boxes what little money they felt disposed to. The amount was never burdensome to the hospital, and never exceeded one hundred dollars a year. In 1877 a person was employed by the hospital to see every person who came for treatment, and asked them if they could afford to pay for medical treatment or not? If not, they were at once admitted after giving their name and address. Those who said they could pay, were asked to give according to their means, but less than twenty-five cents was not desired. Those who could pay a dollar and over were told not to come again after the first visit, as they were not of the class for whom the department was opened, but that they must seek advice outside, at the physicians' offices. This did not result in any

diminution of patients, and in a short time but very few could afford to pay over twenty-five cents. This system is not satisfactory and seems to act as a premium on deceiving. In November, 1877, a competent and experienced man was employed to investigate the condition of all who came to the department from Boston (old city) and South Boston. The result was as follows: number of visits, 386; number of deserving poor, 254; number giving wrong addresses, 79; number amply able to pay, 53. Of the fifty-three able to pay, nineteen owned their houses and other property in the city. The number giving wrong addresses were classed as undeserving, as is the custom in other cities and countries; with these and those able to pay we have one third of the whole number considered as undeserving applicants. The Massachusetts General Hospital Dispensary gives no medicines only in extreme and recommended cases.

The Boston City Hospital Dispensary, when first opened in 1864, furnished medicines and advice free to all residents of the city who applied. In 1869 (?) they stopped giving medicines except in the most extreme cases. They continue the same plan at present, and strive to exclude non-residents.

The classes of people who come for advice and treatment are nearly the same in the three mentioned dispensaries, and are as follows: (1) The needy and deserving poor; (2) those who come because they can be treated free, or nearly so; (3) those who come for free examination and opinion, to see if they are being treated correctly by their own physician; (4) those sent by their physician for free examination, to find out what really is the matter; (5) and last, patients brought by their physicians to get a free consultation. All of these classes visit the different dispensaries, but the last three classes are found more in abundance at the City Hospital and Massachusetts General Hospital dispensaries, and particularly so at the Massachusetts General Hospital, as *one third* of the patients there come from outside of the city, some even as far as forty miles away.

Let us for a short time see what has been done in similar conditions in England. The subject had received much attention prior to 1870; in that year at a meeting presided over by Sir William Fergusson, at which one hundred and fifty-six members of the medical profession were present, the following resolution was passed:—

"That this meeting is of opinion that there exists a great and increasing abuse of out-door relief at the various hospitals and dispensaries of the metropolis which urgently requires a remedy; and, that in the opinion of this meeting, the evils inseparable from the system of gratuitous medical relief administered at the out-door department of hospitals and in free dispensaries can be in great measure met by the establishment on a large scale of provident dispensaries throughout the kingdom and by improved administration of poor-law medical relief." Following this were meetings of various societies, and in April, 1875, the following memorial, of which I quote only a part, was made to the president and committee of council of the British Medical Association: "We, the undersigned, members of the British Medical Association, and others, beg most respectfully to request the committee of council to take into consideration the relation of the medical profession to the hospitals and free dispensaries throughout the kingdom. Your memorialists are convinced

that the manner in which these institutions, with some few exceptions, are at present conducted inflict a serious injury upon many most deserving members of our profession; while the indiscriminate (or almost indiscriminate) bestowal of gratuitous medical relief upon all applicants lowers the whole scale of our professional remuneration, it is far from being a real boon to the working classes themselves, and cannot fail in the long run to have a prejudicial influence upon the nation at large." At this time investigation was made as to the number receiving free medical aid in London, and it was found that one fourth of all the inhabitants were receiving free medical care. In a report of the Medical Committee of the Charity Organization Society I find the following: "It is the out-patient departments of hospitals that are most abused, and it is in these departments that your committee desire to see the indiscriminate relief at present given largely curtailed." They believed that this could be done without seriously affecting the supply of cases which are needful for clinical instruction at those hospitals which have medical schools attached to them and without limiting the true province of Christian charity.

"Under the present circumstances, when there are in the metropolis about one hundred and five hospitals and dispensaries to which the artisan or laborer can turn at any moment, and which may almost be said to be bidding against one another for his patronage, it is obvious that the inducements to providence and self-reliance are entirely taken away. This state of things your committee regard as a very great evil, and they believe that there is no one class of charities which is doing so much to pauperize the population, to undermine their independence and self-respect, and to discourage habits of providence as the medical charities. The committee are well aware of the great benefit that these institutions, if properly used, are capable of conferring upon the humbler ranks of our population. These benefits it would be difficult to exaggerate, but the committee deplore the almost indiscriminate relief which is given."

The outgrowth of this movement in England was the establishment of provident dispensaries, which I presume are more or less familiar to all of the society, and I will only briefly describe them. They do not care for those provided for by the poor-laws, or what we call paupers, but receive those of the lower middle class who, under the ordinary circumstances of life, can care for themselves, but are unable to obtain medical care when sickness comes. This class pay a small amount each month, say a shilling or twenty-five cents, and then when sick are cared for by the provident dispensary, who, on being notified of the case, send some of their physicians, who, in turn, are paid a small fee by the dispensary. Thus the patient has proper medical care, and the physician is not deprived of his entire fee. The result of these provident dispensaries has been most satisfactory, according to recent reports.

Should any change from the present course be deemed advisable, to my mind the first and most important step to be taken is the earnest, hearty, and complete coöperation of all the hospitals and dispensaries in some one distinct plan of work.

When the associated charities were first started I hoped we could find aid in this work from them, but further thought and examination induces me to believe that such aid as now organized would entail so much delay that suffering would follow.

The provident dispensaries are quite satisfactory in England, but from my imperfect knowledge of them my impression is that the detail and machinery connected with their working would render them impracticable here at present.

My last suggestion — and the one in which I have at present the most faith — is that of a competent and experienced paid inspector at each of the large dispensaries.

Such an officer should examine each and every person who applies for treatment, and should have power to exclude *all* except the deserving poor. He should personally examine each case, and after the hours of admission to the dispensary should devote the remainder of the time to visiting and examining into the condition of those who have been treated, in order to ascertain if they are as represented — poor and deserving people.

VITAL STATISTICS IN MASSACHUSETTS.

THE report on the births, marriages, and deaths in Massachusetts for 1879, made under the direction of the secretary of state, and edited by the secretary of the State Board of Health, Lunacy, and Charity with the assistance of Dr. D. F. Lincoln, has recently been presented. The summary of the facts, there stated, is as follows: —

POPULATION.

The rapid rate of increase of the population of the State from 1870 to 1875 (2.538 per cent. annually) was very largely due to immigration by land and sea, which reached its highest point in 1873. The succeeding depression, which began in 1873, was greatest in 1876, when there was a considerable emigration from the State, quite exceeding the immigration. The census of 1875 showed 191,561 more people in the State than in 1870; the natural increase by excess of births over deaths was 55,307, leaving 139,251 to be accounted for by immigration. There came to Boston by sea 130,205, and large numbers must have arrived by land, for many of the immigrants by water simply passed through the State. Those who came overland represent, to a certain extent, a floating population, who go to and from our cities and towns for employment. The extreme industrial depression of 1876 drove many of them from the State. It has seemed fair to suppose that the population did not increase at all during 1876, and only a few thousands in 1877; while the excess of births over deaths (9935), it is thought, would cover all the increase for 1878. An estimate of population consistent with a consideration of the vital statistics of the last five years, during which there has been a gradual annual decrease in the number of births from 43,996 to 40,295, and in deaths from 34,978 to 31,801; while the marriages fell, though not so uniformly, from 13,663 in 1875 to 12,893 in 1878, the increase to 13,802 in 1879 being an indication of the returning prosperity, and consequent increase of population since 1878. The estimate for 1879 has been placed at 1,717,200, the census of 1880 showing a population of 1,783,812.

BIRTHS, MARRIAGES, AND DEATHS.

There were recorded, in 1879, 40,295 births, 13,802 marriages, and 31,801 deaths; or 913 births *less* than in 1878, 909 marriages *more*, and 498 deaths *more*.

The excess of living births over deaths, as recorded, was 8494, indicating a natural increase in the population of 1441 less than in the previous year. The estimated population for the middle of the year 1879 (1,717,200) would give the following rates for that year:—

Births	23.46 to 1000 of population.
Marriages	8.04 " " " "
Deaths	18.52 " " " "
Excess of births over deaths	4.95 " " " "

The same assumed population would indicate one living child born to every 42 persons, one married in each 62, and one death in every 54 living.

In 1873, the year when the expansion following the war had reached its climax, and when the material prosperity of the people had attained its highest point, the number of marriages (16,137) was the greatest ever recorded in the State. In the succeeding year, naturally, the number of births (45,631) was the greatest; while still one year later the great comparative mortality of infants asserted itself by a larger number of total deaths than in any other year except 1872, when typhoid fever, measles, whooping-cough, and small-pox showed the greatest number of deaths in ten years; when scarlet fever was thirty per cent. more fatal than for the average of those years; and when the proportion of deaths from "zymotic" diseases to the total from all causes rose from twenty-three to nearly thirty-one per cent.

The progressively decreasing rate of increase of the population since 1860 is indicative probably, in part at least, of the fact that native Americans who remain in the State have smaller families now than those who formerly constituted its population.

BIRTHS.

During the years 1863-65, which were most influenced by the war, the birth-rate was low (24.08). In the years 1872-74 the rate was higher (28.28), when the expansion and extravagance following the war had reached their greatest height, and the influx of foreign laborers showed its greatest influence. There has been a considerable decline in our birth-rate in the twenty-nine years. The birth-rate for 1879 is 1.27 per 1000 less than for 1878, is less than that of any previous year, and is 3.65 per 1000 less than the average for twenty-nine years. During the sixteen years, 1864 to 1879, 53.6 per cent. of the births occurred during the latter half of the year, 46.4 per cent. in the first half; 23.02 per cent. in the first quarter, 23.31 in the second, 26.76 in the third, and 26.88 in the last. In 1879 as in 1878 and 1877, and for the aggregate of the previous twenty-five years, the general law of an excess of male over female births found expression in very nearly the same proportions (105+ to 100).

ILLEGITIMATE BIRTHS.

Seven hundred and sixteen births were recorded as illegitimate in the State during the year 1879, with an increasing population. During all the years of the recent industrial depression (1873-1878), the rate was unusually high, while the annual number of marriages declined in the same period very nearly one fourth. During the last seven years the reported number of illegitimate children born in the State has been much higher than ever before. In England, on the contrary, the foreign country most similar to ours in laws and social customs, there has been a progressive improve-

ment in that respect, the rate per 1000 of births having steadily diminished from 59 in 1867 to 47 in 1877, still remaining, however, three times as great as the average of our worst seven years, 1873-79.

MARRIAGES.

In 1879 the marriages recorded were 13,802, as compared with 12,893 in 1878, 12,758 in 1877, and 12,749 in 1876. The rate for these three previous years had been lower than at any other time since 1849. This decrease and the following increase are probably due in great part to fluctuations in the business prosperity of the country.

DEATHS.

From 1875 to 1878 there was an annual decrease in the number of deaths from 34,978 to 31,303; in 1879 there was an increase to 31,801. The death-rate fell from 21.17 per 1000 living in 1875 to 18.78 in 1878, and 18.52 in 1879. It is thought that few deaths escape registration now, and that under the new law the causes of death are more accurately stated than formerly, although there is still room for improvement in that respect.

The year 1879 has been one of average good health. No great epidemics have occurred. Of the five diseases noted in last year's report as having been prevalent and fatal to an unusual degree, measles has hardly prevailed at all in a fatal sense, whooping-cough and dysentery have diminished a good deal, diphtheria and croup somewhat. Scarletina, however, caused twice as many deaths as in 1878. Cholera infantum has steadily diminished for four years, and now the deaths are but little more than one half what they were in 1875. The number of deaths registered is a little larger than that for the past three years, but the death-rate is the lowest since 1869, and is 0.7 below the average of thirty-one years.

In 1879 the deaths of females exceeded the deaths of males by 514; 15,628 of the latter having been reported, and 16,142 of the former (unknown, 31). This proportion, 96.8 to 100, is chiefly due to the excess of females over males in the population (857,529 to 794,383, showing an excess of 63,146 in 1875; in 1865 the excess was 63,011, and in 1855 it was 32,301). In the three State-census years, 1855, 1865, and 1875, the ratio of females to males in the population was respectively 105.87, 110.46, and 107.95.

Of the total mortality, a trifle under one fifth was of infants under one year of age; a little over one third was of children under five. By comparing the last ten years' results, it is found that the infant proportion has been quite small for the past three years, a fact which is partially compensated by the smaller number of births in those years.

The deaths from "zymotic" diseases—those commonly considered as most indicative of the sanitary condition of a country—were in 1879 fewer in proportion to the others than in any of the other years; constitutional diseases were proportionately more fatal than the average; local diseases caused a very much greater mortality than in any other of the ten years; developmental diseases for the last four years have held a position much lower than the average; and violent deaths occupied the usual place.

Dysentery and whooping-cough were less fatal than usual; diphtheria and cholera infantum remain at the head of the list, as for the previous three years, but

with a considerable annual decrease since 1876; the mortality from measles was extremely low; typhoid fever, dysentery, measles, and cholera infantum showed very much the lowest death-rates obtaining in the decennial period, while the total deaths from the nine above-mentioned causes number 1313 less than the average for ten years, and only 23 more than in 1879, with a population, probably, at least 260,000 greater.

Of the principal *local diseases*, the increase in those of the central nervous system is striking. The increase in deaths from heart diseases is due probably in part to the same cause which increases nervous disorders, and in part to more accurate registration. The mortality from bronchitis and pneumonia, of the *pulmonary diseases*, has increased at a more rapid rate than the population.

The order of fatality of the principal twelve *causes of death* for the year is as follows: *Consumption* maintains, as usual, the first place. *Pneumonia*, as in 1874, 1875, and 1878, is second; in 1872, 1873, 1876, and 1877, it was third. *Diphtheria* maintains the same position as in the previous year, having declined from the second place in 1876 and 1877. *Heart Disease*—too often a vague term—stands fourth, although only sixth to eighth in the preceding seven years. *Old age* is fifth, and holds a tolerably steady relation to the diseases, being, since 1872, fourth or fifth. *Cholera infantum* has steadily declined from the second place in 1872 and 1873, the third in 1871 and 1875, the fourth in 1876 and 1877, fifth in 1878, to sixth in 1879. *Paralysis*, as in 1877 and 1878, occupies the somewhat high place of seventh. *Cancer*, too, has risen from the tenth, eleventh, and twelfth places, to the eighth. *Scarlet fever* is higher than last year; in 1874 it was fifth, in 1872 sixth, and in 1875 and 1876 seventh. *Cephalitis*, *bronchitis*, and *apoplexy* are rather high. The twelve causes of death constituted 59.38 per cent. of the total mortality of the State for the year.

Typhoid fever has shown the extraordinary decline from fourth place in 1872, sixth in 1873, seventh in 1874, eighth in 1875 and 1876, ninth in 1877 and 1878, to *thirteenth* in 1879. The other prominent causes of death appeared in the following order: Convulsions, 589; croup, 559; atrophy and debility, 574; tabes mesenterica, 511; infantile, premature, etc., 492; drowning and lost at sea, 461; hydrocephalus, 439; Bright's disease, 435; enteritis, 392; dropsy, 380; dysentery, 372; diarrhoea, 370; whooping-cough, 302; casualty, 300.

Considering the five principal causes of death for the various ages, diarrhoeal diseases of the hot months, diphtheria, pneumonia, scarlet fever, and obscure diseases, largely of the brain and intestines, characterize the first period. From five to ten the infectious diseases and obscure diseases of childhood occupy the most prominent places; pneumonia is less prominent. From ten to fifteen, consumption and typhoid fever follow diphtheria. From fifteen to twenty, consumption occupies the first place; typhoid fever is second; pneumonia is prominent from thirty upwards, and heart disease is next; cancer is in the list only from forty to sixty; paralysis and apoplexy gain more prominence from forty upwards; and, over seventy, the greatest portion die of old age.

In *infancy* diarrhoeal diseases caused nearly one seventh of the total mortality; diphtheria, nearly one tenth; pneumonia, as last year, a little over one fif-

teenth; scarlet fever, one eighteenth; and obscure diseases of which the prominent symptoms are referred to the central nervous system, not far from one twentieth. In *childhood*, diphtheria, croup, and scarlet fever caused more than one half of the whole number of deaths; pneumonia and brain diseases, next in order, were very much less fatal than in the previous period. From *ten to fifteen*, diphtheria is at the head of the list, without the great prominence it had from five to ten; consumption, typhoid fever, and scarlet fever are next; while brain diseases do not appear. From *fifteen to twenty*, consumption causes nearly one half of all the deaths; typhoid fever, heart disease, and pneumonia follow; diphtheria falls out of the list, and child-birth appears. Consumption appears as causing more than half the deaths from *twenty to thirty*, and thence upwards of less and less importance up to seventy, when old age is the first cause. From the same age (twenty), through life, pneumonia stands second, with a very uncommon prevalence and fatality for the year; heart disease and paralysis become more frequent; typhoid fever and child-birth reach their highest points between the ages of twenty and forty. The excess of mortality from pneumonia, diarrhoea, and contagious diseases in early life, the great fatality of typhoid fever from fifteen to thirty, and the high death-rate from consumption from youth to the age of fifty, are very striking.

Small-pox was most fatal in midwinter. Measles gradually increasing from October to July, the diminution apparently appearing about the time of closure of schools. Scarlet fever increases from September to March, and then declines. Diphtheria is least fatal in summer, most so in early winter; the possibly kindred disease, croup, following the same law, but more irregularly. Typhoid fever increases suddenly from July to August, September, and October, when the decline continues to June. Dysentery, like cholera infantum, prevails in hot weather. The highest mortality from consumption is in March; the lowest, in the pleasant month of June. Pneumonia increases steadily from August to March, and then declines.

RECENT PROGRESS IN THE TREATMENT OF DISEASES OF CHILDREN.¹

BY D. H. HAYDEN, M. D.

ON THE MANAGEMENT OF INFANTILE ECZEMA.

DR. L. DUNCAN BULKLEY read a paper upon this subject at the annual meeting of the Medical Society of the State of New York, held February 3, 4, and 5, 1880,² including under this head all cases occurring in children of five years old and under, and starts with the proposition that this disease invariably signifies an error of some kind which medical thought should avert, and that it is, like any other aberration of health, a condition of affairs which medical skill should remove! In nursing children the cause of the trouble will commonly be found in the mother. She should never, while nursing, be allowed to take any fermented liquors, and the quantity of tea drunk often needs cutting down. The free use of milk is regarded as the best food upon which the mother may form milk. It is necessary to be on one's guard that the breast milk

¹ Concluded from page 61.

² Transactions for 1880.

is not too weak to sustain the child properly, in order to promptly remedy this should such be the case. When necessary to supplement the milk the author continually gives cod-liver oil, or, where it can be had, cream. The oil may be administered by intunction, using either cod-liver oil, linseed oil, or sweet-almond oil. The numerous errors connected with artificial feeding require attention if we really desire to effect a permanent removal of the disease.

For the constipation which often accompanies infantile eczema the author uses lactopeptine in doses sufficient to produce the desired effect, given two or three times daily, or after each meal, suspended in orange-flower water or dry on the tongue. In the beginning of a case nothing suits so well, for the robust and ruddy-faced child, to unload the bowels and make an impression on the eczema, as calomel. For this purpose, for a child under one year of age the dose employed is one grain rubbed up with a little sugar or bicarbonate of sodium. The dose should be increased by half a grain for each additional year of life. The powder may be repeated every other day, if necessary, given, preferably, in the morning. It need often be given only once or twice a week, or even only as occasion may demand. Any irregularity of the bowels, and especially any tendency to pulmonary congestion, should at once be treated by one of these powders. If the tendency to constipation is not thus overcome the diet must be modified to suit the individual case. Sometimes to avoid starchy food animal food is given in too large proportions.

In the medical treatment alkalies play a prominent part, and are well borne by young children. In case of nursing infants the author generally gives the mother fifteen grains of acetate of potash with nuxvomica and a bitter infusion three times daily after eating. He is very fond of using with the milk Vichy water, using it freely, and when the bowels are constipated he has a siphon of Kissingen water and one of the Vichy provided, using them conjointly in sufficient doses. Children also do well with a few drops of liquor potassæ, — two to five drops to the tumblerful, according to the age. Where there is a good deal of restlessness at night, and the skin is rather dry and hard, he gives the acetate of potassium three or four times daily, in doses of one to five grains in a teaspoonful of the liquor ammoniæ acetatis, and if much arterial excitement be present he adds a drop or a part of a drop of the tincture of aconite.

Arsenic acts well in these cases given to a child one year old in one-drop doses three times a day. Any gradual increasing of the dose is not recommended. In combination with the other measures arsenic should seldom if ever be neglected in the treatment of eczema. After the first year of life the author uses this considerably in conjunction with wine of iron. The French arsenical mineral water, the eau de Bourbonne, is often very serviceable, and children may take a small wineglassful alone or with the milk.

Besides alkalies, cod-liver oil, and arsenic, iron must never be forgotten. Wine of iron, the ammonio-citrate, tartrate of iron and potash, and dialyzed iron are especially applicable. Rabuteau's tasteless syrup of iron is also valuable, and very acceptable to children; also the syrup of the hypophosphites of lime, soda, and iron. The syrup of the iodide the author does not use so much as some do, for he has seen it very ineffectually employed by others. In dispensary

practice very many children with eczema receive the standard rhubarb and soda mixture (one grain of each in a teaspoonful of peppermint water). This well-tried combination is too much neglected in private practice for the substitution of more agreeable and less serviceable remedies. The older French writers speak very well of the extract or tincture of viola tricolor, and this remedy has been lately revived. The author has no experience to offer on the subject. The exact indications for these various remedies are only to be learned by a careful study of each *patient*, who, it must be borne in mind, we are to treat rather than the *disease*. There are, however, tolerably clear lines of distinction between classes of cases which call for an alkaline and depurative treatment and those where cod-liver oil and more powerful tonics are at once demanded.

The remainder of the paper is taken up with a careful consideration of the local treatment, and "he is poorly qualified," the author writes, "to treat infantile eczema who knows only oxide of zinc ointment, and that as directed to be made in the Pharmacopœia." The official ointment often irritates the skin. Cold cream is a better vehicle than lard, — better even than unguentum petrolei or cosmoline; but this latter, as well as glycerite of starch, is preferable to lard. The proportion of oxide of zinc (one in six) is often too strong, and the author seldom employs it stronger than one in eight, and far more often one in sixteen. The tincture of benzoin is also omitted by him, as it sometimes irritates.

The old-fashioned tar ointment is a remedy that has fallen into unmerited neglect. As directed in the Pharmacopœia (equal parts of tar and suet) it is far too strong, but tar, diluted with three times its quantity of cold cream, and oxide of zinc added in the proportion of half a drachm to one drachm in the ounce, forms one of the most valuable antipruritics in eczema. Thus made it can be applied to a very young child with the happiest effects. Subnitrate of bismuth forms a very good ointment in the strength of half a drachm or a drachm to the ounce. Tannin, also, acts very happily where there is a dry, red, and somewhat scaly surface; likewise a weak precipitate ointment.

Too frequent washing does harm, and it is generally preferable that the baby should be wiped off as much as cleanliness demands. When baths are used medicated ones are recommended, the author employing a mixture of carbonate of potash, carbonate of soda, and powdered borax, equal parts. Of this mixture two to four teaspoonfuls should be employed for each gallon of water with about half that amount of starch. Lycopodium should be used afterwards over the whole surface if there is a tendency to the development of acute papular eczema. When the parts are at all acutely involved they should not be washed oftener than once or twice a week. Cod-liver oil is a valuable agent for penetrating and removing crusts when thick. Poultices should never be used except where the crusts are obstinate, and then only for a night or two, removing the crusts in the morning and immediately reapplying the ointment.

When the eczema has lost its very acute elements we may, as in the adult, resort to stimulating applications. For this purpose Hebra's compound tincture of green soap is of great value, composed of equal parts of oil of cade, green soap, and alcohol. It can be diluted with water at the time of using if too

strong. The surface is to be quickly but firmly rubbed with a cloth dampened in it, then dried off, and the appropriate ointment immediately applied. When this is used it is better to have the ointment laid on on a rag, as the extra friction might be too much. This is an excellent antipruritic, and is preferred to that used by many consisting of zinc ointment rubbed up with oil of cade. The addition to each ounce of one drachm of the tincture of camphor or a few grains of powdered camphor often increases its antipruritic properties. Stronger ointments are sometimes called for, but the danger is rather that they will be too strong than too weak. In cases of localized thickened patches the author uses a good deal the unguentum hydrargyri rubri oxydi diluted with three times its quantity of cold cream. Even thus diluted he has repeatedly seen this to be too irritating, exciting fresh papular eruptions. Citrine ointment, diluted three, four, or more times, will also be well borne where the patches are chronic and infiltrated.

The author desires to show in his paper that "oxide of zinc ointment and arsenic are not the only weapons to be employed against this very frequent and distressing disease, and that as it depends upon many causes the measures for its relief must be multiform." It is also desired to call attention to its frequency, and to the neglect with which it is so often regarded by the physician, and consequently by the laity; likewise that its cure should be and will be, if properly accomplished, followed by or accompanied by the improvement in health of the patient, and that therefore there is absolutely no danger in curing infantile eczema.

PERINEPHRITIS IN CHILDREN.

Dr. V. P. Gibney, of New York, reports¹ fifteen cases of this disease in children: these cases are a continuation of nine in a paper in the *American Journal of Obstetrics and Diseases of Women and Children*, April, 1876, of three in another paper in the *American Journal of the Medical Sciences* for April 1877, and of one in the same journal for October, 1878, thus completing a total of twenty-eight.

The following remarks are appended to the clinical records of the cases:—

In typical cases the disease generally begins with a rigor or two, febrile exacerbations more or less severe, according to the acuteness of the attack, lancinating pains in lumbar region, loss of appetite, and general indisposition. In fact, the invasion does not differ materially from that of other acute inflammatory lesions, unless, perhaps, the pain be more localized; and if the child be very young the locality of the pain is not discovered. Constipation is always present. Very soon we have preternatural immobility of the spine, a stooping forward, with elevation of the shoulders. After a week or ten days spasm of the psoas muscle occurs, and the gait becomes characteristic of that so commonly regarded as the second stage of hip-joint disease. The urine is of high specific gravity, and is loaded with urates. The tumefaction appears and the pain becomes excruciating. If an exit be given to the pus a speedy recovery follows; if this be delayed, and the contents of the sac be really pus, it burrows along the cellular tissue, producing an immense abscess. A spontaneous opening is effected, and the convalescence is protracted. If, on the other hand, the inflammatory process has not

resulted in suppuration the contents are most likely serum, and resolution is effected.

In twenty-seven of the twenty-eight cases the disease ran its course in an average period of about three and one half months. The analysis gives: two cases terminating in one month, three in six weeks, eight in two months, six in three months, two in four months, three in five months, two in six months, one in one year, while one seemed to extend over a period of two and one half years.

In sixteen there was suppuration more or less extensive, while in twelve there was no suppuration at all. We see, then, that nearly one half the entire number underwent resolution.

As to the constitutional disturbance produced, in thirteen cases this was very great, and at times very alarming, in eight it was moderate only, and in six was very slight. The complications were few. In one there was an alarming hæmorrhage, easily controlled, however; in one there was a cellulitis of the thigh, or rather a periarthrititis of the knee; one had a femoral abscess, one a subscapular abscess, one a nephritis, and one a pyelitis. In several there was incontinence of urine, and at times painful micturition; yet these are rather symptoms than complications.

In nineteen no exciting cause could be found. In eight the cause was a contusion, a strain, or a fall, while in one a nephritis seemed to be the starting-point. It is the author's opinion that perinephritic inflammation is induced as is inflammation in most other localities, namely, by excesses of heat or cold.

The ages of the patients varied between one and one half years and fifteen. Five were under three years of age, twelve between three and six, eight between six and ten, and three between ten and fifteen.

The sexes were about equally represented; the lesion was on the right side in fourteen cases.

The treatment employed varied a little, yet was chiefly expectant. No specifics have been discovered, and the author is fully convinced that in the management of the cases lay the secret of success. One ran the entire course without medical or surgical aid; and the result is one that any medical man would be proud to get! Four were treated on the purely expectant plan,—no surgical interference, nothing to promote resolution. The general condition of the patient was regarded as the one essential feature demanding attention. Two of these terminated in resolution, two in suppuration, all making perfect recoveries.

The hot-water douche was employed in five cases, and two of these went on to suppuration despite the douche, while three made a speedy recovery, terminating by resolution. Hot fomentations were used in four instances, with good results in two; that is, two got well without suppuration, and the other two got well after abscess. In five cases blistering and subsequent poulticing constituted the treatment, with four recoveries without any suppuration.

An early incision was made in three, a late one in eleven, while in two cases the abscess opened spontaneously. In one instance only was there any delay in recovery and any annoying complication. All, with a single exception, made perfect recoveries, there being some lameness left behind in the one case excepted.

The author in concluding insists on a careful examination, several times if need be, a history obtained without bias, an unalterable conviction that hip disease is from the beginning a chronic and a slowly

¹ Chicago Medical Journal and Examiner, June, 1880.

progressing disease, these points being absolutely essential in making diagnosis. In this connection the author expresses his firm belief that ninety per cent. — yea, a much larger per cent. than ninety — of the cases of hip disease reported as cured without lameness or deformity, cured completely, are not and never have been cases of hip disease, but more likely cases of perinephritis, of perityphilitis, of peri-arthritis, of primary traumatic periostitis, of the various neuroses of the hip, of subacute rheumatism about the hip, or of acute primary synovitis of the hip, all of which affections are insignificant as compared with that terrible malady, with the advanced stages of which we are all so painfully familiar, despite the great improvements in orthopaedic surgery.

At the end of this article is appended a list of the large bulk of authors who have written on the subject of perinephritis.

Hospital Practice and Clinical Memoranda.

CONTINUED TOLERATION OF FOREIGN BODIES WITHIN THE EYE-BALL FOR FIFTEEN AND TWENTY-TWO YEARS.

BY HENRY W. WILLIAMS, A. M., M. D.,

Professor of Ophthalmology in Harvard University.

THE following exceptional and rare cases, which came under my care during the past month, are worthy of record among the instances showing that foreign bodies may sometimes be retained at the fundus of the eye for a long period without giving rise to active symptoms.

CASE I. December 15, 1880, I saw in another city Mr. —, aged thirty. He had consulted me fifteen years before on account of an injury from a bit of gun-cap, which had penetrated his left eye some short time previously, passing through the cornea and iris, and probably through the margin of the lens, to lodge at the deeper parts of the eye. A cicatrix in the cornea near its centre, and a hole through the iris towards its inner part, indicated the direction which the foreign body had taken; but it could not be seen on account of haziness of the crystalline lens. As the eye was then quiet, and free from injection and sensitiveness to touch, I advised no immediate interference; but that the eye should be carefully watched and shown to me at once in case of the manifestation of any active symptoms.

Two years since he came to see me with slight vesication of the cornea of this eye, which yielded readily to treatment.

At present the eye has no perception of light. The pupil is of normal size, and shows behind its lower two thirds a shrunken, cataractous lens; the upper third of its field being clear. Dilatation by atropia does not enable the foreign body to be seen. The perforation in the iris behind the corneal scar is still visible, as when the eye was first seen, fifteen years previously. Below the cornea there was a large bulging of the sclera, which pushed the lower lid outward. The projection had a very dark color, was not translucent when examined with oblique illumination, and the conjunctival vessels over its surface were much enlarged, so that it had been thought possible that a melanotic or other intra-ocular tumor existed. The mass,

however, was easily indented by pressure with a probe; there was no general injection of the globe or vascularity or tenderness of the ciliary region; no tension of the eyeball, and no pain. I therefore regarded the change as a staphylomatous thinning of the sclera.

The case required an operation for the relief of the steadily increasing deformity; the large extent of the staphyloma and the undoubted presence of a foreign body indicating enucleation rather than excision of a part of the globe. After the preliminary dissecting up of the conjunctiva to spare as much of this as possible, the thinned sclera gave way during the division of the recti-muscles, allowing escape of the vitreous, which had become completely fluid; and in the removal of the collapsed globe the bit of copper was probably sponged away with the blood. It was not within the shrunken lens, nor was it found encapsulated at the fundus, as is sometimes the case.

CASE II. Two weeks after the above, I saw J. H. W., aged thirty, whose right eye was penetrated by a bit of gun-cap exploded near him by his brother, twenty-two years since, when he was only eight years old. The eye soon recovered, and remained quiet, with, as he says, considerable vision, until last spring, when he began to have pain and injection of the eye, which continued four months. These symptoms subsided, and he had vision as before until within six weeks, since which time he has had agonizing pain in the circumorbital regions. I found the globe much injected and very sensitive to touch. There was a linear scar near the lower border of the cornea, and a little to the temporal side of this cicatrix there was a hole through the iris, not far from its outer edge. A yellowish reflex, deep in the eye, could be seen through the pupil. No perception of light.

Optico-ciliary neurotomy might have been done, with hope of relief and of the prevention of sympathetic inflammation of the other eye, if the patient could have remained under observation; but as he was obliged to return immediately to his home in Maine, enucleation was performed. The foreign body was found at the fundus, near the antero-posterior axis of the globe, enveloped in the yellowish mass of limited extent, which had previously been seen through the pupil, a process of suppurative softening having evidently begun in the inclosing material. The relief from pain was immediate, and the patient returned home two days later.

15 ARLINGTON STREET, January 13, 1881.

A CASE OF CONGENITAL TOTAL COLOR-BLINDNESS.¹

BY HUGO MAGNUS, M. D., BRESLAU.

EXTENSIVE as has already become the literature of color-blindness, yet cases of entire absence of the color-sense are extremely rare. Hence the value of any such when carefully observed and recorded.

Miss C. S., a lady teacher thirty-eight years old, not a Jewess, came to me during the past year to have her

¹ Centralblatt f. Augenheilkunde, December, 1880. Translated for the JOURNAL by Dr. B. Joy Jeffries. Two very interesting cases of red blindness in one eye from Dr. Hippel and Professor Holmgren, and a case of monocular violet blindness from the latter will be presented to the readers of the JOURNAL, whom they will interest, as also scientists, in reference to the Young-Helmholtz theory of color-perception. A case of monocular total color blindness is reported in the JOURNAL, May 6, 1880.

color-perception examined. She is perfectly healthy, and has not the slightest symptom of hysteria. Every bodily function is normal, except the sense of color, which has always been wanting. She comes of a large family in which color-blindness is prevalent. Of eight children, three — two brothers and herself — were color-blind. As to the precise character of these two brothers' defect the lady cannot give exact data. She thinks one brother, who has meantime died, was like herself totally color-blind. She is convinced of his defect from practicing with him, comparing sensations, testing with colors, etc. This was also confirmed by the several professors of the university whose lectures he attended. Such proof is not of course absolute, but is of value in reference to our case. The parents were certainly *not* color-blind, and *not* blood relatives. The grandparents also were normal-eyed as far as I can find out through my patient.

The lady herself is very confident that she has been totally color-blind from earliest childhood. She cannot recall having seen colors, and cannot associate the loss of color-perception with any serious disease. The fact of the two elder brothers being color-blind seems to have induced the parents to have had those coming after carefully tested, leading to the very early discovery of the patient's defect.

From childhood she has had great intolerance of light. She sees better towards dark, being quite blinded by full sunlight. That this is not due to scrofula is proved by the patient's always having been as she now is. She has, moreover, never had any periodic trouble of the eyes. She suffers still in daylight when it is strong, and wears a colored glass for protection till dark comes. Her deceased brother suffered in the same way.

The lady's visual power is poor: right eye $\frac{1}{2}$, left $\frac{1}{3}$, not improved by any glass. She is myopic dioptries 2.50 (concave glass of 15 inches' focus) in each eye. Visual field normal. With Förster's photometer she requires an illuminating surface of 2.33 mm. square. There is then slight nystagmus. The ophthalmoscope reveals not the slightest pathological change in either eye, but a perfectly normal fundus. Her hair is dark brown; the iris grayish-blue, and reacts normally. Distance between the pupils 56 mm.

As to subjective sensations, the patient says she cannot see any color. Colors vary to her only in being lighter or darker. In sorting bundles of variously-colored worsteds she is guided only by similarity in shade. The whole world appears to her but different shades of gray. The spectrum (in reference to which we shall speak again further on) she describes as simply an illumination consisting of varying degrees of brightness. From one point of greatest brightness the light decreases to each side, so that the impression she has of the spectrum is exactly that of a penciled drawing shaded out darker and darker each side of a bright line. From most careful tests and examination I am convinced that the patient sees no one color from which she can get any sensation other than that of simply more or less light. In Becker's case of monocular total color-blindness¹ *brown* appeared to the person as a color. Our patient has no one color-impression, each and all appearing to her as gray only. Her visual sense is but the feeling of light and darkness and the intermediate gradations.

The various objective methods employed to test the

subjective sensations confirmed the diagnosis of total color-blindness. They were as follows: Holmgren's *Test I., with the light green worsted*. To this was matched bright red, bright yellow, bright blue, gray, bright bluish green.

Test II., with the purple (magenta). As like it were matched various shades of brown and olive-green.

Test III., with bright red. Brown and purple were placed as identical.

Test with blue. To this were matched as identical green, yellow, and pale purple.

Test with yellow. As identical were laid out blue, gray, and purple.

In sorting the worsteds the patient repeatedly asserted that she was guided in her choice of this or that skein simply by the relative brightness of the individual bundle as compared with the test bundle selected.

Examined by the spectroscope, the lady declared she had only a sensation of light, as was previously noted. She said she saw an illuminated band in which a portion was particularly bright, the light shading off from here to either side, more rapidly towards the red end of the spectrum than towards the violet. This shading away from the brightest portion of the spectrum was to her so even and gradual as to recall to her the most careful shading of a pencil drawing. She could not get from the large collection of worsteds the special spectral impression, saying that the gradations in the spectrum were too *gradual* to be matched by the worsteds. The best description she could give of the impression the spectrum made on her was that of a very carefully shaded pencil or chalk drawing from white to black.

The spectrum was not shortened to her at either end, but recognized as far each way as by the normal eye. The greatest brightness was for each eye in the sodium line. These two important points, namely, no shortening and place of greatest brightness, I determined by repeated tests at various times on different days, and always with the same result.

The examination of the individual colors of the spectrum resulted the same, namely, that each gave simply a greater or less impression of light.

Stillings' shadows were all gray to her. No matter what colored glass I used she saw only a lighter or darker shadow. The same with Weber's tissue-paper test.

Stillings' cards, the first edition of which only I had at hand, were not immediately read, but when more carefully examined deciphered with some hesitation.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

DECEMBER 11, 1880. The meeting was called to order by Dr. HODGES at 7.45 P. M.; twenty-six members present.

Dr. F. H. HOOPER reported two cases of subcapsular abscess, attended in one instance by perforation of the lung. The paper was reserved for publication.

Dr. F. C. SHATTUCK said that he had seen both cases, and had been interested in them. When he was told of the first case he thought it one of latent empyæma which had burst through the chest wall as

¹ Translated in this journal, May 6, 1880, page 441.

well as into the lung; an examination had shown that this was not so, but that it really was an abscess which had opened into the lung. He did not agree with Dr. Hooper in thinking that there was a cavity in the lung, but thought rather there was a fistulous tract communicating with a primary bronchus.

Dr. F. L. KNIGHT said that he had never seen such a case. He had been much interested in the cases of peripleuritic abscess reported by Bartels, and thought that Dr. Hooper's might be classed with these, although he admitted that the reader's explanation was a fair one. He thought it a little singular that such cases had not been more frequently reported.

Dr. MORRILL spoke of a case in a young girl ill with phthisis, where a cavity in the lung had opened externally through the chest wall. It was not a case of empyema.

Dr. BLODGETT asked if the abscess in Dr. Hooper's case might not have originated from some necrosis of the under surface of the scapula. He thought that in necrosis the abscess might form without any symptoms acute enough to call attention to it.

Dr. HOOPER said that he was not aware that necrosis could take place without more acute symptoms than were present in this case.

Dr. HODGES said that subscapular abscess was of frequent occurrence in horses, probably of traumatic origin due to sprains, and thought that the same thing might be caused in a child by wrenching the arm. In the Polish case the cause was attributed to carrying a heavy weight.

Dr. HOOPER then presented a larynx from a little girl one year and nine months old. She had had measles six weeks ago, since which time she had been ailing, having a constant but not severe cough. When called to see her a week ago, he found her with a cough of a decidedly "crowing" character and "crowing" breathing. The pharynx was healthy, and there were no glandular enlargements. The child was pale, but was playing on the floor. She was so much improved on the second day that he discontinued his visits, but in a few days was summoned again, to find her in about the same condition as at his first visit, with perhaps the laryngeal symptoms more pronounced. The respiration was crowing and quick, with a shrill cough. Yesterday symptoms of laryngeal stenosis were still more marked, and the condition was such that tracheotomy was performed. After this the breathing was easier, and she slept until two o'clock this morning, when she began to cough and grew cold. Considerable mucus was coughed up through the tube. She died at six o'clock.

Before opening the larynx it was seen to be completely occluded by the swelling and exudation. On section, the mucous membrane was found red and roughened, the aryepiglottic folds were swollen, and an exudation could be seen in places. The trachea was healthy. The pharynx had been free from exudation throughout the trouble, and there were no glandular enlargements.

Dr. CORNELL reported a severe case of cholemia in a young woman twenty-four years of age, which had yielded to a mixture of valerian with Hoffman's anodyne, after treatment with various other remedies had failed.

JANUARY 8, 1881. Forty-one members present. Dr. R. M. HODGES in the chair. Dr. J. H. WHITE-

TEMORE read a paper entitled, Are Free Dispensaries, Abused? ¹

In the discussion which followed, Dr. HICKS and Dr. CORNELL called attention to the great extent of the evil, and instanced a number of cases in illustration.

Dr. STREET said that he once had the misfortune to have a dispensary district, and had had excellent opportunities to know the extent of the abuse of medical charities; if there were any unconvinced he would cite a few cases out of many which had come to his notice. He thought that this wholesale medical aid breeds indolence, poverty, and crime, and demoralizes the community beyond imagination; that the Massachusetts General Hospital makes a great mistake in charging twenty-five cents, thereby leading people to understand that such a fee is all physicians think their services are worth, and that they are paying for what they receive. According to the statistics quoted in the paper just read, it would appear as though the day was approaching when everybody would avail themselves of the privilege of free treatment. The Boston Dispensary had improved their finances by charging ten cents for medicine furnished. This helps the apothecaries, not the doctors. Dr. Street proposed a plan which, in lack of better, might be of service. "I would have cards giving the name, age, residence, and occupation of the person applying for medical charity, and stating that said person is worthy of gratuitous medical aid for a period of sixty days to six months, the time being filled in by the physician giving the card; because a patient, although not now able to pay, at a future time may be; under this system I would have no one treated at the out-patient department of any hospital or dispensary unless a card is presented; when given the party should understand that he can receive treatment at any hospital that he prefers; when presented I would have such hospital stamp it; it could not then be used at another. In that way an interesting case would not be lost by going to another institution. These cards I would have distributed by physicians only, and no one able to pay would ask his doctor to give him a card for free treatment; neither would any suffer for the whole territory of the city is covered by the district physicians of the Dispensary, and if any family is not acquainted with a doctor, they can call on these physicians for a card."

Dr. E. W. CUSHING stated that he saw grave objections to the plan proposed of restricting the advantages of public medical charities to those bringing cards from members of the Massachusetts Medical Society.

It was doubtful whether the trustees of the City Hospital, representing the city government and the public, would ever consent to such an arrangement, so that it would either be necessary to invite coöperation in the use of cards on the part of all "other physicians," or to urge the medical staff of the City Hospital to enter on a course of opposition to the public authorities which might develop into something very like a medical strike. It is not likely that either alternative will be found judicious.

Dr. Cushing was of opinion that if the clinics were much restricted it would proportionately increase the number of those who employ physicians and never pay them, a large band of persons, who can never be made to pay until physicians in general are much stricter in demanding and receiving their fee when their service is rendered.

¹ Vide page 77 of the Journal.

Many of the most interesting hospital out-patients come from a distance, and cannot get at home the special treatment required, while they are of value for purposes of special study and instruction.

The real difficulty lies deeper, and consists in the fact that twice as many young men enter medicine in the city as can reasonably expect to succeed therein. Nothing will ever limit the number of physicians except the bitter suffering, from hope deferred and real pecuniary want, inevitable to the struggle for existence.

If any sweeping restrictions are made in our medical charities, in the face of medical custom everywhere, it can only be accomplished with difficulty and after much discussion; then it will be represented that Boston is a paradise for doctors, because the clinics do not spoil business, and enough more physicians will come here to bring incomes back to starvation limits. We shall have lost our reputation as an extraordinarily charitable and humane profession, we shall have interfered gravely with the study of the specialties in Boston, and greatly injured the school — *cui bono?* — in order that a few more physicians may struggle along together, gracefully hiding by urbanity and professional etiquette the grim difficulties of getting a living out of their profession.

DR. BARNES thought there could be no conflict between the homœopathic and regular schools, as we were concerned merely in the abuse of our own institutions, and in its prevention.

DR. KINNEAR said that the Associated Charities had registered 20,000 of the very poor in the city, and that the card system had been used with success.

DR. PARKS approved of Dr. Street's plan, and thought the objections to it not serious; that the abuse of medical charity told most severely on the younger men in the profession, and must be fought by them; that the root of the evil was that physicians did not conduct their practice on business principles, — they were too delicate to insist on their pay. He had made a careful study of this abuse, while doing district dispensary work, and had come to the conclusion that at least one third of such applicants were unworthy.

DR. PRINCE thought the card system would merely shift the responsibility to the district physicians, as they could not be expected to give the necessary time to form an intelligent decision.

DR. CUSHING stated that agents of the Associated Charities existed in nearly all the wards, and would be glad to coöperate in remedying this abuse.

DR. FARLOW said that the apothecary had been instanced as always a gainer; he wished to call attention to the undertaker. It was often true that a family who could not pay the doctor could pay the undertaker.

DR. C. M. GREEN spoke of a number of cases of abuse of medical charity which he had seen.

DR. BIGELOW said it was easier to see the evil now under discussion than to devise its remedy. It is not limited to this country, nor is it new. The main alleged difficulty is that the medical profession is defrauded of fees by persons who, being able to pay for medical advice, procure it gratuitously from institutions under a false pretense of poverty. The argument that such institutions considerably encourage pauperism had little weight with him. Pauperism may be increased by the indiscriminate giving away of money, but hardly of medical advice. If anything justifies promiscuous charity it is sickness. Still the injustice done to the medical profession may be, upon

a small scale, a real one. The principal remedy suggested to-night is that cards or certificates should be furnished to the worthy poor by physicians. A fatal objection to this plan is that the judge of pauperism in such a case should be a disinterested party, and that a physician may not be so. Another remedy proposed to exclude the doubtful class is a fee exacted from all who can pay. This has been tried by the Massachusetts General Hospital, and has been found to make such patients feel that they have a right to have advice at a minimum price. The experiment is about to be abandoned. A certificate of worthiness from a central board of charity is not free from objection. In the emergency of illness it could not be waited for, nor could the judgment of such a board be permanently relied on for the proper distribution of cases to different institutions. This opens another consideration: the rights of medical men who give their time to public institutions. They treat with equal care all applicants, but justly prefer cases of scientific interest. Such cases should not in any way be sifted off or withheld from a general service attended by them. This consideration is also of the first importance for the education of the student, in behalf of whom a small sacrifice may be fairly asked of physicians. Dr. Bigelow strongly favored the plan of Dr. Whittemore, the able superintendent of the Massachusetts General Hospital, of appointing an efficient officer at a good salary to devote his whole time to sifting applicants. But the existence of friction in admission to one out-patient department would only drive patients to another. There is no remedy for the existing evil here without the coöperation of all our local institutions. It should be distinctly recognized that the present honest effort to correct an alleged injustice to the medical profession comes in the first instance and spontaneously from the trustees of the Massachusetts General Hospital, but Dr. Bigelow could not learn that other institutions in this city were prepared to coöperate in this or in fact in any movement to diminish the size of their out-patient departments.

Recent Literature.

Practical Histology and Pathology. By HENEAGE GIBBES, M. B. Philadelphia: Presley Blakiston. 1881.

The author of this little work has endeavored to give in a small space a set of practical rules to guide those wishing to learn to work with the microscope. He does not aim at originality, but at giving the results of his experience with various methods. Most workers are apt to have their favorite modes of hardening, staining, mounting, etc., and to make little use of others that may be equally good. This is probably the reason that in this work many points are not touched on. The part which has interested us most, and we imagine the author, also, is that devoted to staining. Mr. Gibbes mentions many aliline colors that are but little used, and gives directions for double and treble staining. This is a branch which offers a wide field for study, and this book will be a useful guide to beginners in it. Our own experience has been that most methods of double staining are very unreliable, and the results transient. Any one who will overcome these difficulties will do a great service to histology. We hope Mr. Gibbes's studies will be carried further both by himself and other observers.

Medical and Surgical Journal.

THURSDAY, JANUARY 27, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to

Houghton, Mifflin and Company,

No. 4 PARK STREET, BOSTON, MASS.

THE HARVARD MEDICAL SCHOOL DURING 1879-80.

THE annual report of the president and treasurer of Harvard University for 1879-80, which embraces reports from the officers of the different departments of the university, contains interesting information concerning the Medical School.

The whole number of students in attendance during the year was two hundred and sixty-three; during the first term, two hundred and fifty-six; during the second, two hundred and thirty-nine. Of these, one hundred and twenty-one had a literary or scientific degree. There were seventy-four applicants for the degree of Doctor of Medicine, of whom ten withdrew their names, and nineteen were rejected. Forty-five passed the examinations and received their degrees.

Since their establishment in 1877, English and any one of the five subjects, French, German, algebra, plane geometry, and botany, have been added to the two subjects, Latin and physics, formerly required in the examinations for admission.

The results of these examinations since 1877 are given by Dr. Ellis, dean of the medical faculty, in the following table:—

	1877.				1878.				1879.				1880.

In commenting on the effects of these preliminary examinations the president of the university says:—

It is notorious that medical students have been, as a rule, a rougher class of young men than other professional students of similar age. In this university, until the reformation of the school in 1870-71, the medical students were noticeably inferior in bearing, manners, and discipline to the students of other departments; they are now indistinguishable from other students. A corresponding change in the medical profession at large would be effected in twenty years, if all the important medical schools of the country should institute a reasonable examination for admission.

In regard to the four years' course of study in preparation for the degree,—a plan adopted by the medical faculty during the past year,—the course being recommended to all students, though not prescribed, the president remarks: "This measure has grave inconveniences; for it makes it necessary to maintain in the school a three years' course and a four years' course at the same time. The four years' course is not made by simply adding another year to the three years' course, but differs from the three years' course in important respects from the beginning of the third year, and differs somewhat even in the second year. Two full years from October, 1880, must therefore elapse before there can be a proper fourth year's class, composed of persons who have planned from the beginning of the second year to remain four years in the school. Again, so long as it is possible to get the degree in three years, some students will crowd their studies into that period, in spite of the advice of the faculty, to their own disadvantage and the injury of the school. Furthermore, the trouble and cost of maintaining the two courses simultaneously are much greater than the trouble and cost of maintaining the longer of the two courses by itself." Notwithstanding these drawbacks, the faculty preferred to maintain the three years' course for the present, and to make the adoption of the four years' course optional with the student. It believed that the advantages of the four years' course would be so conspicuous that all the more intelligent students, who were not straitened in their circumstances, would adopt it, and that the school would then gradually pass from one system to the other without suffering any very serious reduction of numbers. The president believes that these reasonable anticipations can hardly fail to be realized in due time.

In discussing the question of clinical instruction, the number of teachers having been considerably increased of late, and this branch of study having an especial importance in a fourth year, he says: "The most valuable clinical instruction is that which two or three students at a time receive from a skillful instructor, who allows them to see, touch, and listen for themselves. If it be said that it is impossible to give such personal instruction in a large school without a great number of clinical instructors, the answer is twofold; first, that the number of clinical instructors ought to be as large as the community can well supply; and, secondly, that the university should be more concerned to have a very good school of medicine than a very large one. The faculty fully realize that the task to which they have this year addressed themselves is a difficult one; but their experience during the past ten years, in similar attempts to improve medical education, encourages them to expect a favorable issue in their present undertaking. They confidently rely upon the coöperation of intelligent students, and of observant parents who have sons in the school, and upon the support of all the best-educated part of the medical profession."

We are very glad that the university is not only willing, but able to take so dignified and elevated a position. We would have nothing sacrificed to mere

numbers; but though the number of students should remain comparatively small,—and, as a fact, we believe it has slightly decreased during the past year,—we do hope that in some way the funds of the medical school may be made to grow with its reputation, so that eventually the zealous devotion of assistants and instructors may be less a labor of love and expectancy. If rumor speaks truly, the teaching of medicine in Philadelphia is, like the carrying trade of some of our great Western railroads, so prosperous, that the temptation to the construction of parallel roads to learning is irresistible.

A certain competition is doubtless desirable, and in Boston would not be without its uses; but we are afraid to carry the foregoing simile farther, for the inevitable reduction in rates and schedule time in reaching a medical degree, always attendant upon a multiplication of schools, does not inure to the advantage of the public.

The dean of the faculty gives a table which we regret is too extended for insertion, in which will be found the statistics of rejections in different subjects at the annual examinations of the school in June for the past four years. The statistics, however, show the general recognition by intelligent students of the advantages of spending the whole time to be devoted to medical studies in a school properly equipped for giving instruction, as may be seen from the following table, with which the dean closes his report.

NUMBER OF TERMS SPENT AT THE SCHOOL BY GRADUATES.

	Spent six terms.	Spent five terms.	Spent four terms.	Spent three terms.	Spent two terms.	Total graduated.
1872	3	0	8	18	27	56
1873	5 per cent.	3	14 per cent.	32 per cent.	48 per cent.	41
1874	22	2	6	5	3	38
1875	14	7	6	0	3	30
1876	47 per cent.	5	4	2	10 per cent.	36
1877	25	13 per cent.	11 per cent.	5 per cent.	9	61
1878	69 per cent.	9	8	1	3	61
1879	40	4	3	0	0	45
1880	65 per cent.	2	3	2	1	70
	41	2	4 per cent.	2 per cent.	1 per cent.	
	85 per cent.	1	4	0	1	45
	62	2 per cent.	5 per cent.	2 per cent.	2 per cent.	
	88 per cent.	1				
	39					
	86 per cent.					

We sympathize with the regret expressed by the president of the university that similar statistics are not published by other prominent medical schools, and hope that they may be stimulated to an honorable rivalry accompanied by such a "fair count" as may make the figures really valuable for comparison.

—Mr. Luther Holden, a few days since, delivered his last clinical lecture at St. Bartholomew's Hospital previous to retiring from the post of acting surgeon to this institution, after a service of more than forty years.

OUT-PATIENT ABUSE AND THE PROFESSION.

DR. CHALMERS, writing of the abuse of charities and the tendency of indiscriminate alms-giving to pauperize a nation, expressed his belief that there was no danger of overdoing medical relief for the poor; that people were willing to become paupers if they could be supported in idleness, but that no increase in hospital accommodations could increase the amount of disease. Were the distinguished divine alive to revise his writings he would find it necessary to add a note to the effect that unlimited sick relief tended to increase the number of those willing to accept its benefits, and was not an exception to the general rule as to the debasing effect of indiscriminate giving.

It has lately become the fashion to condemn almost universally the out-patient charities of the hospitals and dispensaries, and many members of the profession seem to look upon them as simply a system of robbery, by which they are deprived of a legitimate source of income. That abuses exist there can be no question; but there are certain reciprocal relations between the dispensaries and the profession at large that do not seem to have been sufficiently considered. In the first place, no matter how guilty the dispensaries may have been themselves in "extending their usefulness," the general profession has contributed very largely to their enormous growth.

Almost every physician in the cities must have found it more convenient at some time to refer a patient to the dispensary than to treat him,—perhaps the patient was a troublesome one, or the doctor had not the time to unravel a puzzling case, or he preferred to send it to a hospital that had a special department devoted to similar cases. It may have been a perfectly legitimate method of disposing of the case; but so far as that patient or his friends were concerned, it threw the influence of the doctor in favor of a charitable institution.

Again, certain physicians wish it to be known that they practice only for those who can pay. Sometimes it may be they demand their fee in advance, and patients who can no longer pay are sent in a sort of disgrace to receive charity. Such a patient finding the reality not very disagreeable, influences others, and they in their turn their neighbors, till no one can calculate the result of that one refusal to give charitable advice.

Physicians at a distance send patients for gratuitous consultations at the hospitals, teaching them how to take advantage of the out-patient departments with which their student life has made them familiar, and are surprised to see others follow whom they have not sent, and in their complaints that the metropolis absorbs all their important cases, forget that they themselves have helped to bring about the result.

On the other hand the out-patient system relieves the busy practitioner of much responsibility. The patient who paid his fee regularly for years and is now destitute, the superannuated nurse, the worn-out domestic, all the numerous dependants whom the prosperous man gathers about him, and who look to him for medical direction, are cared for, for him, by the

younger generations of dispensary physicians. Suppose the dispensaries closed, what an amount of work would be thrown upon the general profession which they could not conscientiously throw aside. What a number of patients unable to bear the burdens of sickness, and yet not paupers, would appeal for aid. It would be but a short time before the custom of former years would be forced upon certain members of the profession, of opening their offices upon certain days for free treatment of such as chose to apply; a custom superseded by the out-patient system but undoubtedly equally abused in its day.

We have made no attempt at the solution of the problem how to do away with the abuses complained of. We have tried to show that the profession as a whole has a responsibility in the matter and that the abolition of the dispensaries would bring to the profession at large additional burdens and would not do away with the abuse. The inference is not hard to draw, the profession as a whole needs to encourage the feeling of independence and pride on the part of people able but not always willing to pay for medical attendance, and to take care that those who have paid and will be able to do so again do not, in the period of temporary poverty, form the habit of getting assistance without return.

That is, the coöperation of the profession as a whole is desirable in treating the subject. The hearty coöperation of the three largest charities could probably be secured for such a scheme as that proposed in the article we publish to-day, although the abuses at the City Hospital are observable among the in-door rather than the out-door patients, and the dispensary has already reduced the attendance by one third. We would gladly do something to attract the notice of each and every medical man to his personal responsibilities in the matter.

MEDICAL NOTES.

— Dr. Charles F. Folsom has resigned his position as a member of the Massachusetts Board of Health, Lunacy, and Charity, and Dr. Alfred Hosmer, of Watertown, has been appointed to the vacancy. The appointment is a very excellent one, but we fear that no fitness of individual members, however eminent in certain departments, can be made to counteract the inherent defects of the present organization of that Board.

— An examination for three resident physicians for the Western Pennsylvania Hospital, to serve for one year from April 1, 1881, will be held at the hospital, Pittsburgh, Penn., on the fourth Wednesday in March.

— A Hospital Sunday Society has been recently formed in Lowell, with Dr. Nathan Allen as chairman. We quote a portion of their plan of organization:—

(1.) The third Sunday in January each year is recommended as the most convenient day to be observed as Hospital Sunday. (5.) Upon the third Sunday in January it is expected that every clergyman will preach a charity sermon, setting forth the condition and needs of the poor and suffering in our

city, and take up a collection for their relief, allowing every person, by envelope or otherwise, to designate the object of his charity; each church shall also have direction of its own collections so far as they are not designated by individual donors. (6.) If donations are made inside of any church for an object not within the church or parish, they shall be transmitted through the treasurer of the general society; also donations made outside of any church, not designated, may be transmitted to the treasurer, and distributed as the executive committee direct, and be noticed in the annual report of the year.

— In the *Medical Record* for October 30th will be found a report of a case of rapid lithotripsy, in which the patient, aged seventy, died eighty hours after the operation, supposably from "suppression of urine and uremia, resulting from the shock of lithotripsy, — the shock being the result of urethral distention rather than from irritation of the bladder."

— The *British Medical Journal* says: "A most extraordinary and inexplicable piece of blundering came to light at the last meeting of the Kidderminster town council. Certain unpleasant rumors have of late been pervading the town as to the alleged percolation of sewage into the auxiliary well of the water-works; and the borough engineer was, therefore, questioned on the subject. This official was very indignant at the idea that such percolation existed: 'It was simply impossible and absurd to suppose that such could have been the case. The sewage-pipe passed through the well, but the pipe was well cased, so that it was impossible for any sewage to enter the well.' The accuracy of this confident assertion may very well be questioned; but how so extraordinarily perverse a piece of ingenuity as the passing of a sewer-pipe through a well should have been dreamt of, much less carried out and defended, passes our comprehension."

NEW YORK.

— The eighth annual meeting of the New York Training School for Nurses in connection with Bellevue Hospital, which is the pioneer institution of the kind in this country, was held at the Nurses' Home in East Twenty-Sixth Street, opposite the hospital grounds, on the evening of January 11th. There were sixty-three pupils present, and the graduating class numbered twenty-nine members. In addition to their relatives and friends, many prominent ladies and gentlemen interested in the work attended the exercises. The report of the secretary, Mrs. Robert Woodworth, stated that since the opening of the school in 1873 one hundred and twenty nurses had been graduated, of whom one had died, four had married, twenty-four were in positions in training-schools, hospitals, and other public institutions, three were nursing the poor, two had entered sisterhoods, three had been deprived of their diplomas on account of unbecoming conduct, and the others had established themselves as professional nurses in New York and elsewhere.

In 1880 thirty-seven pupils were received, of whom seven proved incompetent. The school has under its charge all the female and two of the male wards of

Bellevue Hospital, and also the Sturges Pavilion and other special departments attached to the hospital. The demand for nurses by private families is greater than the school can supply. There were five hundred and nine such applications in 1880, of which one hundred and eighty-nine were supplied from the school, two hundred and twenty-six were referred to graduates established as nurses in the city, and ninety-four were necessarily refused. At the school a list of all the graduates and their addresses is kept for the convenience of the public, as well as for the purpose of securing employment to the nurses.

—At the stated meeting of the New York Academy of Medicine, January 6th, Dr. Samuel Sexton read a paper on False Hearing and Autophony in Singers, Speakers, and Performers on certain Musical Instruments. On this occasion the annual election of officers also took place, and resulted as follows: President, Dr. Fordyce Barker (re-elected); vice-president, Dr. Robert F. Weir; trustee, Dr. S. T. Hubbard (re-elected). Various members of committees were also elected. During the evening the president announced that Mrs. John Jacob Astor had given \$500 for the purpose of improving the journal and circulating department of the library, and a vote of thanks to Mrs. Astor was passed. The library of the academy, which is open every day from nine A. M. to nine P. M., and is free to all, now contains more than seventeen thousand volumes, and receives regularly one hundred and twenty-two American and European medical journals.

—At a meeting of the Medico-Legal Society, held January 5th, Clark Bell, Esq., ex-president of the society, read a paper on The Coroner's Office, in which he maintained that the office should be abolished, and that of medical examiner, as in Massachusetts, substituted for it; by which arrangement he believed that the desired work could be accomplished at a very much less cost to the public and in an infinitely more satisfactory manner than was now the case.

—Professor Chandler, president of the Board of Health, recently said that it was his opinion, based on careful study, that at least ten thousand died every year in this city solely because they were too much engaged in money-making to see that the water they drank and the air they breathed were not polluted by disease; and as for every death there was an average of twenty-eight well-defined cases of illness, we had two hundred and eighty thousand cases of sickness each year which were equally unnecessary. "But people are beginning to acknowledge," he continued, "that it may be just as well to keep out sewer-gas from their houses as not, and the laws upon the subject of the proper ventilation of soil-pipes in tenement-houses are such that we can now save many persons from sickness in spite of themselves. The Board of Health has been hammering away about the necessity of pure air and the ventilation of soil-pipes ever since it was organized. It may be said to have got to work in 1867. Children under five years of age are the most liable to be killed off by disease arising in this way, and if, therefore, we take the statistics of the deaths of children under five since

1867 to the present time the result of better plumbing may be judged. In 1867 the ratio of deaths of persons over five years of age to those of persons under five years of age was 17 to 53. In 1879 the number of deaths of persons over five years of age was 15,561; and if the same ratio of deaths may be assumed as in 1867, it follows that the number of deaths under five years of age would have been 17,551. But, instead of this there were only 12,788 deaths of persons under five years of age — a saving of 4,773 lives. Leaving out of the question any such conclusion, however, the statistics show that though the city's population has risen steadily in the last twelve years, from 899,092 to 1,171,740, the death-rate among young children for the last three years is actually less than for 1867, 1868, and 1869. This is due largely to proper plumbing in tenement-houses."

—During the last three months there were seventy-eight small-pox patients in the Riverside Hospital, on Blackwell's Island, of whom twenty-nine were discharged and twenty-two died, leaving twenty-seven in the hospital at the beginning of the year.

—Dr. George Ford died on Ward's Island, January 7th, from cancer of the stomach, at the age of seventy years. Dr. Ford organized the State Emigrants Hospital on Ward's Island, with which he was connected from 1847 to the time of his death. Since 1855 he had been physician-in-chief to the institution.

—At a special meeting of the County Medical Society, January 10th, Dr. Charles L. Dana read his prize essay entitled On the Benignity of Syphilis, being a Study of the Disease especially as it affects Seamen. From statistics and a careful personal investigation of the United States Marine Hospital Service he concluded (1) that syphilis, as a rule, ran a mild course in American seamen, and (2) that it often got well without proper treatment, and in spite of the worst hygienic surroundings. Consequently he thought that the syphilitic poison had probably become lessened in virulence, as compared with what was formerly the case.

—Dr. Clinton Wagner, of New York, has been appointed professor of diseases of the throat and nose, and Dr. William J. Morton, of New York, professor of diseases of the mind and nervous system, in the medical department of the University of Vermont.

—On New Year's night one of the Nautch dancers, who arrived a few weeks ago from Hindostan, and said to be only in her thirteenth year, was delivered of a male child, the first Hindoo baby ever born on American soil. The infant weighed only four pounds and four ounces, and lived but a day or two.

—The records of the bureau of vital statistics show that there were 31,866 deaths in this city during the year 1880, an increase of nearly 3500 over the mortality of the preceding year. There was, however, an increase of 1920 in the number of births during the year, the whole number in 1880 amounting to over 27,500. The number of deaths from phthisis was 4769 in 1880 as against 1313 in 1879; from alcoholism, 222 in 1880 and 198 in 1879; from disease of the heart, 1148 in 1880 and 1164 in 1879; from

Bright's disease, 1425 in 1880 and 1348 in 1879; from pneumonia, 2848 in 1880 and 2551 in 1879; from bronchitis, 1395 in 1880 and 1263 in 1879. The suicides numbered 155 in 1880 and 117 in 1879, while there were 242 deaths from drowning in 1880 as against 149 in 1879.

CHICAGO.

— Dr. H. P. Merriman has resigned his position as one of the physicians to the Cook County Hospital. Dr. Lester Curtis has been appointed to take his place.

— There has been during the past two weeks in Chicago quite an epidemic of diarrhea, among people of all ages and conditions. These cases are rarely severe: they last only a few days, and are mostly painless. The epidemic is now (January 13th) passing off. With this tendency to diarrhea has come frequently duodenal and gastric irritation, that has made a large number of people sick. Some tenderness in the epigastrium, occasional slight pain, and vomiting, and in a few instances symptoms of icterus have characterized these cases. A few days' rest and abstinence from food, with very little medicine, have sufficed for the recovery of most of the cases. Quite a large proportion of these attacks are among business men.

It has been endeavored to explain these wholesale attacks of sickness by charging that our drinking-water from the lake tunnel was polluted, but a most thorough examination of the water supply has developed the fact that it was never purer, and that no city is furnished with a better article. Whatever might justly have been said of it last spring, when some contamination from the city sewers did reach out to the crib two miles in the lake whence our supply comes, it is certain that now it is a drinking-water that is ideal.

There has been offered the theory, too, that as bad sewers and bad ventilation often make people sick, and as Chicago always has a lot of bad sewers and many badly ventilated houses, therefore these must explain the epidemic referred to. As all the unsanitary conditions we have have existed through the months and years past, with only slight fluctuations in degree of badness, and as latterly they have not been worse than usual, of course all such theories are failures.

— Dr. O. C. Oliver, pathologist to the State Insane Hospital at Elgin, Ill., died a few days ago of typhoid fever. The profession has sustained in him a serious loss. He was young in years, but his life had been devoted to the most thorough preparation for original work in pathology. Had he lived there is no doubt he would have made his mark in this field. He had been for several years curator of the museum and director of the histological laboratory of Rush College, and had become very proficient in micro-photography. He spent a year abroad in the study of pathology and biology; returned a few months ago, and accepted the new position which he occupied at the time of his death. Very few of the profession in Chicago were well acquainted with him, but those who knew him best knew that beneath an exterior of modest de-

meanor there was an ambition for knowledge and excellence that is always admirable.

— Our annual visitation of a wail from our neighboring towns along the Illinois and Michigan Canal and the Illinois River has not failed to come up this winter. This wail is a just one. We cannot and do not complain that the people of the injured cities and villages find fault, and we would say to them, If you sent us annually such odors as we send you, we should not only wail, but we would strike back. Chicago is a city now free from bad smells. The blessed river is frozen over, the open ditches are frozen up, and for some reason the rendering works in the outskirts are still, or, rather, well behaved, and the air sweeps across us from the prairies as fresh and pure as that from the mountains. But our sewers still empty into the river, and the river empties thousands of cubic feet of water per minute into the canal, which flows down toward the Illinois River, carefully preserved from any loss of odor by the covering of ice, till it reaches Joliet, forty miles away, where the locks are, and the water flows over a dam, and of course comes in contact with the air. The result may be imagined. The people of Joliet say no one can fully appreciate it without a residence within reach of the dam, and as the wind shifts all the people of that city find in turn that they are within reach of it. It must be very bad, as these temperate people are in search of more adjectives with which to describe their affliction. Other towns suffer in like manner, but none so sorely as Joliet.

There is only one remedy for all this, namely, more dilution of our sewage as it passes into the canal. This means either pumps here to force more water into the canal, or the deepening and enlarging of that channel to a ship canal. Something of this sort we are coming to inevitably. In the summer, when for forty miles the water in the canal is exposed to the oxidizing influences of the atmosphere, there is no complaint. All classes of people are advocating one or both of these remedial measures; the money necessary for pumping works is already appropriated; the belief in the West seems unanimous that a ship canal we must have eventually. Yet the law makers and the law executors find obstacles and reasons for delay that make our relief seem distant indeed.

— Small-pox is increasing in our midst, not to an alarming extent, but enough to stir people up to a wholesome desire for revaccination. The superintendent of schools has, on the recommendation of the health commissioner, ordered that hereafter no pupil shall be admitted to the public schools without a physician's certificate that vaccination has been performed within seven years. This is a most wise step, and the surprise is that it has not been taken before. Heretofore a pupil was admitted with a vaccination certificate at six or seven years of age, the vaccination having been made in infancy, perhaps, and thereafter in his case no attention was paid to the matter, notwithstanding the testimony of experience that vaccination to be protective must be repeated every five to ten years.

Nearly all the vaccinations now made here are with bovine virus. Indeed, the writer would find it impossible to name a physician who uses from choice the humanized virus.

While the bovine virus generally "works" more vigorously, and often produces enormously swollen arms and severe constitutional symptoms, there is no prejudice against it among the people. For these severe results the profession is never blamed. Under the old practice with the humanized virus a bad arm always led to criticism, often to severe censure, of the practitioner, and not a little practice changed hands as a consequence.

Miscellany.

PELLETIERINUM-TANNICUM AS A REMEDY FOR TENIA.

MR. EDITOR, — So far as my observations have extended, the profession, as well as myself, have long felt the need of a more reliable taniacide than has yet been found in the use of filix mass, kamula, turpentine, pepo, or the ordinary preparations of pomegranate.

This want is now well supplied by the alkaloid or active principles of the bark and rind of the pomegranate.

Having had occasion recently to test the latter in a family with four cases of tenia, I am convinced that the active principles of the pomegranate as now prepared are the remedies *par excellence* for this parasite.

In the *Practitioner* for December, 1880, appears a short account of the drug: It says: M. du Jardin-Beaumetz read a paper before the French Academy of Medicine upon the use of the drug, and in reference to its use as a remedy in tapeworm he declares that the sulphates of pelletierin and isopelletierin possess energetic taniacide properties, when exhibited in doses of 0.30 grain in a solution containing 0.50 of tannin; since, in the great majority of cases (thirty-seven times out of thirty-nine), they caused the expulsion of the parasite, with its head.

Laboulléne used it in nineteen cases, and secured the head in every instance. The preparation which I used was the pelletierinum-tannicum, procured by my local druggist from Gehe & Co., of Dresden. It comes put up in small bottles, containing a single dose of one and one half grams of the powder.

There was no griping pain or other unpleasant sensations in the bowels, which so often attends the use of the other taniacides, and the only unpleasant effects noted were (as expressed by the patient) "a cracking headache and quite a profuse perspiration." The latter may be readily accounted for from the fact that the drug produces more or less cerebral congestion.

According to the two French authorities quoted, out of fifty-six trials of the remedy there were but two failures in securing the head; hence it would appear that in the sulphates and tannates of pelletierin we are likely to find as perfect a specific against tenia as we can hope for.

I forward this brief sketch of the drug for the benefit of those who, perchance, have not become acquainted with it, either by its use or through the columns of some of the various medical journals.

G. S. STEBBINS, M. D.

SPRINGFIELD, MASS., January, 1881.

QUARANTINE BILL.

UNDER the title of Quarantine Bill, or the Last of the Louisianas, the *Cincinnati Lancet and Clinic* publishes a sensational sanitary tale of the period, from which we extract the opening part of Chapter II. : —

"Quarantine Bill was sitting in his richly furnished office, at the corner of St. Louis and Royal Streets, on a hot day in August. He was amusing himself reading one of Gilson's beautiful essays on How to Skim Yellow-Fever Germs from the Top Layer of Disinfectants. A bland smile played across sweet William's features, and he softly murmured: 'This is equal to Bell's method of boiling up a man-of-war in steam, and ironing it out afterward in a navy-yard laundry. I much prefer the refrigerating method; a frozen ship on ice, like a quail on toast, has charms for me. I believe in the old flag and an appropriation of one hundred thousand dollars for the germ-freezing experiment. When germs are valued at a dollar apiece they are worth looking after.' Tilting his chair back, he pulled out a carbolic-acid cigar, and tenderly touched it off with a sulphur match; a few bacterians, wafted up from Plaquemines Parish, grew sick at the stomach, turned up their saffron-lined bellies, and dropped dead on the floor. 'Strange!' muttered Quarantine Bill, 'how easy it is to kill a bacterian, how hard it is to find a germ. If the yellow-fever germ is ever discovered, my days are numbered along with those of Yellow Jack.' A thousand curses on the National Board of Health and their too inquisitive agents! The audacity of the United States government sending a fever commission to Cuba is damnable. Their agent, Sternburg, is even now in this city experimenting in germ culture, and God only knows what he may discover. White and Bemiss are traitors to render him assistance. Do they wish to rob the city of New Orleans of her principal medical attraction, Yellow Jack? Do they wish to make the Crescent City great, healthy, prosperous, and destroy the living of a few Creole doctors? Mon Dieu! Parbleu! Nouvelle Orleans n'est pas parfait sans la fièvre Plaquemines.' He expectorated a thin stream of abuse on a small unopened package marked Bulletin of National Board of Health, and subsided into momentary silence; only momentary, however, for he almost immediately commenced to hum that beautiful Louisiana legislative *chanson* : —

Oh! a source of wealth
Is our board of health,
When New Orleans grows ill.
For each politician
Discovers the mission,
Of jolly old Quarantine Bill.
Chorus.
Here's to Yellow Jack!
May he soon come back.
We wait for him expectant.
Until summer is over
We live in clover
On the price of our disinfectant.

"A knock was heard on the door. Quarantine Bill ceased singing, and shouted, 'Come in!' Yellow Jack entered after making a profound bow. On his entrance William jumped up, and grasped the welcome visitor's feverish hand. The thermometer on the wall promptly jerked its mercury up to 105° F.; a cloud of wiggle-waggle germs appeared upon the slide of a microscope in the corner; the urine in the test-tubes precipitated albumen; all the office, in fact,

seemed to respond to the presence of the dread visitor. 'Welcome! Welcome! Yellow Jack, when did you arrive from Havana?' queried Quarantine Bill, as he handed his guest a chair."

HERBALIST'S SURGERY.

AN important case came before the Coroner's Court at Old Basford on the 8th inst., which from its surgical and medico-legal aspects is alike important. From the report in the *Nottingham Daily Guardian* we gather that a man, thirty-seven years of age, was suffering from some trouble in connection with his bladder or urethra, and on hearing from a friend of his—Mr. Marlow, a herbalist—that if sent for he could do him good, he sought his aid. The herbalist "attempted to draw his water, but instead of that drew blood." Mr. Maltby, a surgeon, was then called in, and found the man collapsed, in great pain, and passing bloody urine; he quickly developed symptoms of peritonitis, from which he died. At the autopsy no urethral stricture was found, but there was a false passage, about three inches long, from the urethra, and piercing the neck of the bladder, which was probably the exciting cause of the fatal peritonitis. It is obvious that considerable violence must have been employed in this case, and while forcible catheterism is not justifiable, even where the passage is obstructed by a stricture, it is still less pardonable where there is no obstruction at all. The fact that skillful surgeons sometimes make false passages in front of tight strictures has no bearing whatever on such a case as this, where there appears to have been no obstacle whatever to the passage of an instrument properly used. The surgical point in the case, however, is obvious, and we need not further allude to it. The coroner was at great pains to instruct the jury as to the principles by which they were to be guided in coming to their verdict, which was that the man died from peritonitis. It is to the coroner's law that we would specially call attention. He said "a mistake had been made," but that Marlow could not be held to be criminally responsible. He argued that as the operation of passing a catheter has been done very frequently by patients for themselves, it was an operation which an unskilled friend was qualified to do for the deceased. But he seems to have lost sight of the fact that Marlow offered his services to the man with the assurance that he could relieve him, and there can be no doubt that he gave the patient the impression that he was skilled in the treatment of such cases, and professed to be qualified to pass a catheter. Had he possessed a qualification to practice, an action for mal-praxis would undoubtedly have laid against him.—*Lancet*.

PURE BOURBON WHISKY REDIVIVUS.

It happens now that the difficulty of obtaining pure Bourbon whisky, properly aged, is about to be done away with in what we think a very practical manner.

The Newcomb-Buchanan Company distillery at Louisville is the largest distilling company of straight whiskies in the Union. Their rank in the United States is similar to that of the four great Dublin firms which gave the name and fame to Irish whisky. In 1873, in view of the fact that the genuine and old Bourbon whis-

kies were being so rapidly exhausted, they erected as a business venture an additional distillery, known as the Anderson Distillery Company, on a large scale, and put into it the best machinery their large knowledge could dictate and their immense capital command. They constructed the original old-fashioned copper stills of former days, and in them they manufactured, from sour mash by open fires, as of old, the Bourbon whisky of former days. This they have stored to obtain age, supplying the demand for new whisky from their other distilleries. The earlier crops of these whiskies are now sufficiently old to obtain a proper excellence, and the best judges in Kentucky have declared that they are fully up to the standard of the best Bourbon of equal years. Acting upon the advice of medical friends, the company have determined to offer these whiskies through the medical profession, and in such a way as to insure consumers that they have not been adulterated after leaving their hands. They will be bottled and sold in cases. Each bottle will be protected and sealed with the trade-mark of the company, which mark will be a guarantee that the whisky contained in the package is old-fashioned, hand-made sour mash, fire-distilled whisky of the Anderson Distillery Company, and not less than five years of age when corked.

Knowing the high character and standing of the Newcomb-Buchanan Company, we can testify to the good faith with which it will perform its promises. As the company has unlimited facilities for introducing their manufactures throughout the United States, there will soon be no community which cannot command genuine and old Bourbon whisky, and this, too, at a moderate cost; for the company proposes to get very little more profit for the bottled whisky than for the same when sold in quantity. Retail dealers may sell it at the same cost or at a very little advance upon that which they have demanded for inferior articles.

We trust good will spring from this move of the Newcomb-Buchanan Company, and that the day is not far off when their guaranteed brand (or that of other equally good Bourbon distillers) will take the place of much of the liquor which goes by the name of whisky in our pharmacies. Certainly it needs but an acquaintance to make its way.—*Louisville Medical News*.

RIGHT HEMIPLEGIA AFTER SCARLATINA, WITH EMBOLISM OF THE MIDDLE CEREBRAL ARTERY, DESTRUCTION OF BROCA'S CONVOLUTION WITHOUT APHASIA, AND DEATH FROM DIPHTHERIA.

At the meeting of the Clinical Society of London, November 26th, as reported in the *Medical Times and Gazette*, December 11, 1880, Dr. F. Taylor related a case of right hemiplegia after scarlatina, with embolism of the middle cerebral artery, destruction of Broca's convolution without aphasia, and death from diphtheria. The patient was aged five years, and was seized two weeks after an attack of scarlatina with hemiplegia of the right side. There was no aphasia; but the boy answered questions intelligently and in long connected sentences. There was sensation in the leg, but not at first in the arm, and there were occasionally attacks, apparently of the nature of convulsions. Two or three weeks later sloughs occurred on the back of

the hand and fingers; later still the right arm and leg became œdematous; and the urine was subsequently found to be albuminous." About nine weeks after the onset of his illness he was attacked with nasal and pharyngeal diphtheria, of which he died in a few days. At the post-mortem examination there was found embolism of the left middle cerebral artery, with extensive softening of the left hemisphere, involving the posterior portions of the second and third frontal convolutions, the lower parts of the ascending frontal and parietal, the supra-marginal convolution, the island of Reil, the corpus striatum, and the anterior part of the inner capsule. The heart showed a few minute vegetations on the mitral valve; it was not dilated. The right kidney had two large embolic infarcts; and the right hand presented over the abductor indicis one large irregular ulcer as a result of sloughing, and three smaller sloughs on the fingers. Dr. Taylor called attention to the frequent occurrence of attacks of cere-

bral hemiplegia in connection with exanthems in children, in many of which no opportunity was afforded for demonstrating the exact manner in which the paralysis was brought about. Thrombosis of the cerebral vessels was considered to be a frequent cause, but this case showed that obstruction of the vessels might also arise from embolism as a result of an acute disorder of the heart. In relation to the persistence of the faculty of speech, it appeared from the history that the child had been *left-handed* in consequence of some enfeebled condition of the right arm, which was noticed from birth. This places the case in the category of those which appear to show that the speech-centre tends to be located on that side of the brain which is most educated for muscular movements. A third point of interest with the case was the occurrence of diphtheria; its late appearance renders it probable that it was independent of the previous infection of scarlatina.

Deaths reported 2721 (no report from Chicago); 1021 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 582, lung diseases 434, consumption 408, diphtheria and croup 246, scarlet fever 118, small-pox 49, typhoid fever 40, diarrheal diseases 30, malarial fevers 27, erysipelas 25, whooping-cough 20, measles 13, cerebro-spinal meningitis 13, puerperal fever one. From *typhoid fever*, Phil-

adelphia nine, New York seven, New Orleans five, Brooklyn, Boston, Pittsburgh, Milwaukee, and Taunton two, St. Louis, Baltimore, Cincinnati, District of Columbia, Buffalo, Lowell, Fall River, Chelsea, and Clinton one. From *diarrheal diseases*, New York nine, New Orleans six, Boston four, St. Louis and Baltimore two, Brooklyn, Cincinnati, District of Columbia, Buffalo, Lowell, Cambridge, and Fall River one. From *malarial fevers*, New York 10, Brooklyn and New Orleans four, St. Louis

and District of Columbia three, Cincinnati, Buffalo, and New Haven one. From *erysipelas*, New York seven, Philadelphia four, Brooklyn three, Boston, Cincinnati, Buffalo, Providence, New Haven, Lowell, Fall River, Lawrence, Salem, Newburyport, and Chicopee one. From *whooping-cough*, New York five, Philadelphia and Brooklyn three, Cincinnati, Pittsburgh, and Lawrence two, Boston, Buffalo, and Lowell one. From *measles*, New York five, St. Louis two, Brooklyn, Worcester, Cambridge, Fall River, Newton, and Quincy one. From *cerebrospinal meningitis*, New York five, Philadelphia three, New Orleans Milwaukee, Chelsea, and Malden one. From *purpuræ fever*, St. Louis one.

One hundred and eight cases of diphtheria, 82 of scarlet fever, six of measles, three of whooping-cough, and one of typhoid fever were reported in Brooklyn; diphtheria 44, scarlet fever 12, in Boston; scarlet fever 27, diphtheria 12, in Milwaukee; small-pox one, in Fall River; diphtheria two, scarlet fever two, in Somerville.

In 38 cities and towns of Massachusetts, with a population of 1,070,975 (population of the State 1,783,986), the total death-rate

for the week was 21.62, against 21.31 and 21.21 for the previous two weeks.

For the week ending December 25th, in — German cities and towns, with an estimated population of 7,698,024, the death-rate was 23. Deaths reported 3396; 1585 under five: pulmonary consumption 458, acute diseases of the respiratory organs 300, diphtheria and croup 177, scarlet fever 73, typhoid fever 59, measles and *rotheln* 53, whooping-cough 48, puerperal fever 20, typhus fever (Danzig) one, small-pox (Breslau) one. The death-rates ranged from 14.1 in Leipzig to 29 in Würzburg; Königsberg 28.1; Breslau 27.7; Munich 25.3; Dresden 22.2; Berlin 24.5; Hamburg 27.4; Hanover 18.6; Bremen 20.5; Cologne 18.4; Frankfurt 20.8; Strasburg 21.1.

For the week ending January 1st, in the 20 chief towns in Switzerland, estimated population 522,856, there were 35 deaths from acute diseases of the respiratory organs, diarrhoeal diseases ten, diphtheria and croup eight, whooping-cough five, small-pox five, typhoid fever two, measles one.

The meteorological record for the week in Boston was as follows: —

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 15, 1881, TO JANUARY 21, 1881.

BAILY, JOS. C., major and surgeon. His leave of absence granted him in S. O. 188, December 13, 1880, military division of the Pacific and Department of California, is extended one month. S. O. 13, A. G. O., January 18, 1881.

COLES, E., captain and assistant surgeon. Having reported in person, is assigned to temporary duty in the office of the medical director of the department. S. O. 1, Department of Arizona, January 3, 1881.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the hall, No. 19 Boylston Place, on Saturday evening, January 29th, at seven and a half o'clock. Dr. Henry O. Marcy will read a paper entitled The Development of the Osseous Callus in Fractures of the Bones of Man and Animals. Dr. A. T. Cabot will open the discussion. Supper at nine o'clock.

All members of the Massachusetts Medical Society are cordially invited to be present, and to take part in the discussion. H. C. HAVES, M. D., Secretary.

Dr G. H. BIRNEY has been appointed gynecologist at the Carney Hospital. Patients in this department are seen at the hospital on Monday and Thursday at two o'clock p. m.

JOHN HUNTER AND HIS PUPILS.¹

ABSTRACT OF AN ADDRESS DELIVERED BEFORE THE
ACADEMY OF SURGERY, PHILADELPHIA, JANUARY
12, 1881.

BY PROFESSOR S. D. GROSS.

In person Hunter was of middle height, but very strong and robust, with a very short neck, broad shoulders, and a broad expansive forehead, denotive of high cerebral development. His eyes and complexion were light, his brows heavy, his cheeks rather high, and, as one of his biographers expresses it, his mouth was somewhat underhung. His hair, in youth, was inclined to red, but as he advanced in life it became gray, and at length partially white. He possessed great powers of endurance and required little sleep, often working, with hardly any intermission, for nearly twenty hours out of the twenty-four. In his manners he was most ostentatious and rather cold and reserved; in his dress plain and simple, and not always particularly neat. He wore, as was then the custom, short breeches, with knee and shoe buckles.² His temper was warm and impulsive, and, although he was naturally kind, he often betrayed ill-feeling, especially when any one "galled his patience," or when he was overcrowded with business, unusually fatigued, or entirely occupied upon some interesting and absorbing investigation requiring uncommon patience, deep thought, or persistent effort. At such times his irritability occasionally got the advantage of his judgment and good breeding. It is related of him that, returning late one evening more than ordinarily worried and fatigued, he found a large party of ladies and gentlemen assembled in his drawing-room. Feeling excessively annoyed at this unexpected sight, he gave way to his passion, exclaiming: "I ought to have been informed of this kick-up, and as I have come home to study I hope the company will now retire," which they of course at once did. He had little taste for society or amusement. And yet Hunter, ascetic as he apparently was, was by no means insusceptible of social enjoyment. When not too intently occupied he took pleasure in the conversation of his friends, loved to talk with his pupils, and often played with his children, taking a lively interest in their studies and amusements. Nay more, he was very fond of animals, and not unfrequently spent hours in watching their pranks, and at times even participating in their sports. Such conduct is certainly not, to say the least, reconcilable with the idea of a bad temper, or a cross, ill-grained disposition. On the contrary, it places Hunter in the very best light of a kind-hearted, if not amiable man; snappish at times, when overworked, but, in the main, thoroughly good-natured. In his boyhood, and even for some time after he settled in London, he was a merry, rollicking fellow, inclined to mischief and to gross hilarity, especially in the dissecting-room, in the company of the noisy students and the resurrectionists,

among whom he always went by the name of "Jack Hunter." One of his favorite amusements was to visit the shilling gallery to assist his boisterous friends in damming an unpopular play, in which he was, it would seem, an expert. He was a great swearer, a practice by no means uncommon in those days, even in polite society,³ and he was often deficient in courtesy, so characteristic of the well-bred gentleman. To his patients he was kind and liberal, and not a few were warmly attached to him. Whatever his faults may have been as a young man, in after years he became more sedate, and found it more difficult to unbend himself. Hence people who met with him only casually, or who knew nothing of his habits, naturally concluded that he was austere and unsocial. His sly humor, however, never entirely forsook him. He was always, even in his later days, fond of a good joke and of a well-told anecdote, and he himself occasionally indulged his fancy in placing things in so ludicrous a light as to excite merriment.

For many years, as previously stated, he spared neither pains nor expense in procuring all kinds of living animals, birds, and reptiles, with a view, not only of studying their habits, but also for experimental purposes, and for the illustration of comparative anatomy and physiology. Even insects were laid under contribution, and the study of the honey-bee was for a long time an object of special interest with him. The numerous specimens which were here accumulated including some in mineralogy, conchology, and even in palaeontology, now grace the museum known by his name, while of many of them an account is to be found either in his collected writings or in the *Philosophical Transactions*. The labors at Earl's Court were not of a flickering or paroxysmal character, but were continued with hardly any intermission through his whole professional career, the daily sustenance and stimulus of his existence. They always formed the early exercises of the day, generally from six to ten o'clock, when he was obliged to abandon them in order that he might earn that "damned guinea," as he was wont to call it, which stood so much in the way of his tastes and his happiness, and yet was so necessary for the supply of his daily wants.

The kind of life led by Hunter was not calculated to make him a popular practitioner. His manners, as stated in a former part of this discourse, were blunt, and he was sometimes overhearing, even to men of his own rank in the profession, or his equals in social position. His colleagues at St. George's Hospital especially disliked him, and the feelings of animosity engendered by his disagreeable conduct occasionally broke out into open hostility. His practice for many years was large and lucrative, and greatly increased in both these respects after he was appointed court surgeon. All accounts go to show that he was most patient and painstaking in the investigation of his cases, and most cautious in the expression of his opinions. If he found himself at a loss in determining the diagnosis, he did not hesitate to acknowledge it and to ask for further time. He would merely say: "I cannot tell, at present, what to recommend; I must think of it." With Hunter, as with every honest and conscientious man, every case

¹ Continued from page 77.

² Of the various portraits that are extant of him that by Sir Joshua Reynolds is by far the best. It represents him as sitting in a chair in deep thought, with a pen in one hand and the other supporting his chin. From this portrait an admirable steel engraving was made by Sharp, a celebrated artist, copies of which were widely disseminated, and still adorn many a surgeon's study. After his death a bust of him was made by Flaxman, in the execution of which he was assisted by a cast taken during life.

³ The habit is perhaps not entirely extinct, even at the present day, in certain parts of England. We have the authority of Macaulay for saying that Wellington invented the expression, "I don't care one two-penny damn;" a small oath, adds the historian, altogether disproportionate to the duke's greatness. *Life and Letters*, by Trevelyan, vol. ii. p. 221.

was a study, not to be lightly passed over, or treated with heartless indifference. He was always particularly condescending to his poorer patients during consultation hours at his own house. No matter how many "grantees," as he called them, might be present, he generally gave precedence to the former, saying they had no time to spare, whereas the others, having nothing to do, could afford to wait. He would sometimes deduct largely from a stipulated fee for an operation if he found that the person had unusual difficulty in raising the money.

Notwithstanding his profound knowledge of anatomy, Hunter never ranked high as an operator. Pott and Bromfield, not to mention others of his London contemporaries, were his acknowledged superiors in this respect, and fully his equal in practical surgery.¹ He was a surgical pathologist rather than an operator; a lover of principles, and a hater of knives. It is said of him that he never invented an instrument, as it was of Cullen that he never introduced a new remedy. The fact is, Hunter had no very exalted opinion of operative surgery. An operation, he remarks, is a reflection on the healing art, a tacit acknowledgment of the insufficiency of surgery.

Whether Hunter was ever extensively engaged in operative surgery does not seem to be known. Largely as he was occupied, for many years, in private and hospital practice, frequent opportunities must have occurred for the employment of the knife, but whether he performed this duty himself, or confided it to others, I have no means of determining. Home refers to two successful operations which he performed for the removal of two huge tumors, one on the head and the other on the neck. The latter was so large, and involved such important structures, that one of the best surgeons in England declared no one but a fool or madman would attempt its excision. There is no record going to show that he ever cut anybody for stone in the bladder. Hunter was one of the first surgeons who taught that the only way of preventing hydrophobia was to excise the wounded structures. The only very remarkable operation with which his name is associated is the one in which he tied the femoral artery for the cure of a popliteal aneurism, a feat which had never been achieved before, and as the procedure involved a new principle it has ever since been designated by his name. The subject of aneurism had long occupied his thoughtful study, and he was painfully aware of the insufficiency of the various methods of treatment in use up to the time when he entered upon the active duties of his professional life. Having ascertained from numerous dissections that the artery in the immediate vicinity of the disease is usually in an unsound condition, he came to the conclusion, after much reasoning and reflection, that the only rational plan was to tie the vessel in a healthy portion of its extent, at the cardiac side of the tumor, and consequently at some distance from it. The first case in which this theory was put into operation was one of popliteal aneurism in a coachman, forty-five years of age, a patient in St. George's Hospital. The operation, a memorable one in the history of surgery, was

performed in December, 1785, and was followed by a complete cure, notwithstanding that four ligatures were applied, instead of one, as is now and as has long since been the custom. Hunter's excuse for this bungling, unscientific piece of surgery was his fear of secondary hemorrhage, not apparently knowing that such an amount of exposure of the artery as the application of four ligatures necessitated would add greatly to the liability of its occurrence and the danger of a fatal issue.

I shall not stop here to inquire into the claims of Hunter to the honor of being the first to perform this operation upon correct scientific principles. These claims have long been generally, if not universally admitted by surgeons, excepting the French, who have invariably ascribed the merit of it to their countryman, Auel. No impartial historian, however, can fail to award it to the Englishman. The case of Auel was a traumatic aneurism of the brachial artery at the bend of the arm caused by the prick of the lancet in venesection. The ligature was applied close to the tumor, and the artery was perfectly sound. Hunter's case was one of spontaneous aneurism dependent upon a diseased condition of the vessel, which was secured in a healthy portion of its extent at a considerable distance from the tumor. In the one case an important principle, the result of deep study and long-continued reflection, was involved; in the other, none. Hunter's deep concern was that after the ligature of so large an artery the collateral vessels might not be sufficient to carry on the circulation in the distal portion of the limb. He had derived some encouragement from an examination of the velvet of the stag's horn, in which there is an enormous development of vessels, establishing an intimate connection between the antler and the integument of the head; but to put this matter fully to the test, he induced Sir Everard Home to tie the femoral artery of a dog, and the result was precisely what he had anticipated. He concluded, moreover, from a careful study of the functions of the lymphatic vessels, that the blood in the aneurism would be gradually absorbed, and here, again, his reasoning did not disappoint him.

It is a singular fact that Hunter foreshadowed the principles which now guide the surgeon in the treatment of club-foot and analogous distortions. While dancing in 1767 he ruptured his tendo Achillis, a circumstance which led him to institute a series of experiments upon the reunion of divided tendons in the dog, by severing these cords subcutaneously with a couching-needle. The animals were killed at different periods, when it was ascertained that the union had been effected in a manner similar to that of a simple fracture. His own tendo Achillis, as was ascertained after death, had united by ossific matter. It nowhere appears that Hunter made any practical use of the knowledge thus acquired, and he cannot, therefore, as some of his admirers have asserted, be considered as the founder of orthopædic surgery, inasmuch as he made no practical application of the results of his experiments, but viewed them simply in their physiological and pathological relations. It remained for Stromeyer, nearly two thirds of a century later, to place the subject in its true light, without, in all probability, any aid from Hunter's experiments, or any knowledge that his attention had ever been directed to the subject.

Upon no surer foundation, I am inclined to think,

¹ It was natural for Home, his brother-in-law, to speak of his operative skill in terms of unqualified praise; but we have the testimony of Sir Astley Cooper, one of his most illustrious pupils, and himself no common operator, for stating that Hunter possessed little or no dexterity, certainly not the least elegance. His anatomical knowledge, however, was very accurate, and this, added to his coolness and self-possession, generally enabled him to complete, although slowly, any operation he might undertake.

rests the assertion of his distinguished pupil, Professor James Macartney, of Dublin, that he was aware of the fact, so strenuously insisted upon by the Irish surgeon and his followers, that wounds, under favorable circumstances, might heal without inflammation. The only passages in Hunter's works which at all countenance this view are the following: "The healing proceeds, without pain or constitutional disturbance, as if nothing had happened;" and in another place he says: "There is only a feeling of tenderness in the part, and that is entirely from the injury done, and not from the operation of union." "In treating of the same subject," remarks Macartney,¹ "he further says that inflammation comes on as a necessary consequence of parts being too weak to unite by the first intention, or not having the power or disposition to heal." How such expressions could be tortured into the idea that Hunter supposed that wounds ever heal without inflammation it would be difficult to determine. Had he entertained such a belief he certainly would not have withheld a knowledge of it from the profession, or failed to give utterance to it in his lectures and writings. It might as well be assumed that Hippocrates had been the discoverer of auscultation, because the idea had occurred to him that diseases might be detected by the sounds emitted by the affected structures. Robert Hooke, the mathematician, and other philosophers, entertained similar views, — views which were not realized until the early part of the present century, when Laennec first applied them in practice. Hunter hit the truth, but failed to perceive its import; and had it not been for his pupil the fact might still be slumbering in the womb of time.

Hunter's doctrines were not well received by his immediate English contemporaries. They could see in them nothing of any particular value, and concluded that nothing good could come out of Nazareth. Many regarded his teachings with contempt, as the offspring of a conceited man, and as nothing better than what they could find in their own libraries. It is not known whether, like Harvey, he suffered in his practice from this cause. No wonder that he was occasionally disheartened. "The few good things I have been able to do," he was heard to say, "have been accomplished with the greatest difficulty, and encountered the greatest opposition."

It is a remarkable fact that, while Hunter was treated with cold indifference, if not positive contempt, by members of his own profession, he received numerous testimonials of esteem and appreciation from learned societies at home and abroad, as well as of friendly recognition from his own sovereign. In 1767 he was made a Fellow of the Royal Society of London; in 1776 Surgeon Extraordinary to George III.; in 1783 a member of the Royal Society of Medicine and of the Royal Society of Surgery of Paris; in 1786 Deputy Surgeon-General of the army; and in 1789, four years before his death, Surgeon-General and Inspector. The Copley medal of the Royal Society, the highest distinction in its gift, was conferred upon him in 1786, in recognition of the value of his services as an original investigator. The American Philosophical Society, the Royal College of Surgeons of Ireland, the Chirurgical Society of Edinburgh, and the Royal Society of Sciences and Belles Lettres of Göttingen enrolled him among their members.

Hunter, after his election to the Royal Society, at-

tended its meetings with great regularity, and enriched its Transactions with many of his most celebrated papers.

Hunter had been engaged almost ever since his return from the army in teaching anatomy and surgery at his own residence; but in 1773 he determined to become a public lecturer, assigning as a reason for the step that his doctrines were often misunderstood or willfully misrepresented, and that, therefore, it was due to himself to place them in their true light before the profession. The lectures were delivered gratuitously during the first two winters at St. George's Hospital, but after this period he charged the same fee as other teachers, and they were thenceforth given in a room in Leicester Square, hired expressly for the purpose at his own expense. They were repeated annually until 1792, when his arduous labors compelled him to resign them in favor of Sir Everard Home, who had long been his private as well as hospital assistant.

As a lecturer Hunter was not popular or particularly instructive. His manner was dull and prosy, and he seldom raised his eyes from his note-book; his statements were often contradictory, and occasionally he lost the train of his thoughts or wandered from his subject. His language, rarely elegant, was at times coarse and even vulgar. Lecturing was a formidable task for him, and he sometimes felt so uncomfortable as to be compelled to take laudanum to compose his nerves. His classes never exceeded fifty, even in his best days, and not one half that number, says Otley, derived much benefit from his teachings.² Many of his pupils, as, for instance, Abernethy, Macartney, Cooper, Thomson, and Physick, became in time the leading spirits of their profession, propagating and extending his doctrines, and reflecting immortal credit upon him as their preceptor and master.

Hunter was a scrupulous observer of punctuality, and he enjoined this precept with peculiar force upon his pupils. He never, if possible, failed to meet a professional engagement, and occasionally became very angry if the attendant was not on time, or if an appointment was made for him without his having been previously consulted. His biographers tell us, what indeed one might have anticipated, that he carried these regulations into his domestic arrangements. His dinner hour was four o'clock, then the custom in London, and that no time might be lost the meal was always served at that hour, whether he was present or absent. He dined very heartily, but seldom drank more than one glass of wine. His habit was to sleep for an hour after

² According to Abernethy, "the more humorous and lively part of the audience would be tittering, the more sober and unexcitable dozing into a nap, while the studious and penetrating appeared to be seriously impressed with the value of Mr. Hunter's observations and inquiries." Macilwain's *Life of Abernethy*, p. 153. New York, 1833.

As an offset of this statement, I may remark that one of his pupils, Mr. Cline, who afterwards rose to eminence, after having attentively listened to Hunter's lecture one day was heard to say: "Ah! Mr. Cline, we must all go to school again." Could a higher compliment than this be paid to a teacher? Hunter, no doubt, occasionally, perhaps frequently, shot over the heads of his pupils.

In his *Hunterian Oration*, delivered in 1824, Cline thus further expresses himself respecting Hunter's teaching: "I had the happiness of hearing the first course of lectures which John Hunter delivered. I had been at that time for some years in the profession, and was tolerably well acquainted with the opinions held by the surgeons most distinguished for their talents, then residing in the metropolis; but having heard Mr. Hunter's lectures on the subject of disease, I found them so far superior to everything I had conceived or heard before, that there seemed no comparison between the great mind of the man who delivered them and all the individuals, whether ancient or modern, who had gone before him." *Life of Sir Astley Cooper*, by B. B. Cooper, vol. i., p. 94. London: 1843.

¹ *Treatise on Inflammation*, p. 10. Philadelphia, 1840.

dinner, after which he dictated to an amanuensis, prepared his notes for the next day's lecture, and retired for the night about twelve o'clock, a very little sleep, usually about five hours, sufficing to set his machinery in order for the coming work.

In 1781 Hunter appeared in court as a witness in the celebrated trial of Captain Donellan for the supposed murder of his brother-in-law, Sir Theodosius Boughton. He was subpoenaed as an expert, but his testimony was so disjointed and contradictory as to render it impossible to deduce from it any rational conclusions. He had either not made himself acquainted with the nature of the case, or he willfully determined not to commit himself. The judge lost his temper, and in his charge to the jury indulged in sarcastic remarks respecting Hunter's conduct, tending to deprive his testimony of any weight it might otherwise have had. "For the prisoner," he said, "you have had one gentleman called, who is likewise of the faculty, and a very able man. I can hardly say what his opinion is, for he does not seem to have formed any opinion at all of the matter." Surely this may not have been the fault of Hunter; no man in his right senses will commit himself in any case if he has not the proper light to guide him, as would seem to have been the truth here.

Great as Hunter was, and disgusted as he was with the pretensions of some of his contemporaries, who spared no means to undervalue and disparage his labors, he was, really, from all accounts, an humble-minded man. He was generally, if not always, distrustful of the accuracy of his own labors, and he seldom allowed anything to pass muster that had not been subjected again and again to the test of experiment, or to the scrutiny of repeated observation and careful analysis. He was not blind to his own imperfections. His constant saying was: "We are but beginning to learn our profession." He committed errors, but they were errors of reasoning, not of observation, a faculty which few men ever possessed in so high a degree. Of system he knew nothing, or at most very little, and in the arrangement of the diversified objects of his museum he freely availed himself of the suggestions of his friends and of the services of trained assistants.

Hunter, notwithstanding his apparently unrefined nature, and the fact that he was always deeply absorbed in his studies and contemplations, was a man of aesthetic tastes. He was, as previously stated, fond of animals, enjoyed a beautiful landscape, and loved to look at fine pictures, of which he had a choice collection, chiefly by the old masters, which, after his death, were sold at auction for eight hundred pounds. He had also a large number of engravings, including many of Hogarth's. His books, many of which were annotated in the margins, brought only one hundred and sixty pounds.¹

Notwithstanding that Hunter enjoyed for many years a large and lucrative practice, as the most renowned surgeon of the English metropolis, it is not surprising, when we consider the vast sums of money which he lavished upon the purchase of objects of natural history and pathological specimens for enriching his museum, that he should have died poor.² It may safely

be asserted that he was the only man who ever paid five hundred pounds for a human skeleton, and this is only one example of his extravagance. Apart from his museum, to the construction of which he devoted so many of the best years of his useful life, he left little at his death but debts.³ To liquidate these absorbed almost the whole of his estate, real and personal. The result was that Mrs. Hunter and her two surviving children were left in such straitened circumstances as to require for several years aid from the king's bounty, kindly procured by disinterested friends. The executors, in compliance with the provisions in the will, offered the museum, in which lay the only hope of their future support, to the government, which, finally, in 1799, six years after Hunter's death, by a vote of parliament purchased it for the sum of fifteen thousand pounds, hardly one fifth of its original cost. By the government the museum was soon after transferred to the Corporation of Surgeons, who, the following year, under a new charter obtained from the crown, assumed the name and title of the Royal College of Surgeons. The funds of the corporation, when this trust was accepted, were in a very low condition, and they would have been compelled to reject it if their new charter had not given them permission, by placing the whole subject of the surgical education of the country into their hands, to examine students for the diploma for membership, which yields annually a large revenue for the increase and support of the museum and of the college.

One of the difficulties experienced in disposing of the museum arose from the fact that, at the time of Hunter's death, the attention of the British government was completely absorbed by the events of the French Revolution. When Mr. Pitt, the prime minister, was consulted respecting it, he exclaimed: "What! Buy preparations! Why, I have not money enough to purchase gunpowder." Through the influence, however, of Lord Auckland and other prominent friends of the family, parliament was at length induced to take it at the paltry sum above mentioned, a number of distinguished medical and scientific gentlemen having been previously examined in reference to its value and importance in a national point of view.

A grant so important was not, as might be supposed, made without certain stipulations. Among these was one that the collection should be preserved at the expense of the college, that the college should at an early day furnish a catalogue, and that the museum should be thrown open, not only to the medical profession, but on two days of the week to the public. In 1806 the council of the latter instituted two annual courses of fifteen lectures each on anatomy and surgery, which are delivered by Fellows of the college specially selected for the purpose. In 1813, chiefly through the influence of Dr. Matthew Baillie and Sir Everard Home, provision was made for the delivery of an annual oration commemorative of Hunter's birthday, a trust which has been sacredly observed ever since. It was the expressed wish of the founders of this oration that while one of its objects should be to

¹ Sir James Paget's Hunterian Oration for 1877, page 39.

² "In the first eleven years of his practice, from 1763 to 1774, his income never amounted to a thousand pounds a year; in the year 1778 it exceeded that sum; for several years before his death it had increased to five, and at that period was above six thousand pounds." *Late by Home.*

³ Hunter directed in his will that, in the event of refusal by the British government to purchase his museum, it should be offered to any foreign government, and this effort also failing, it should be sold entire. In 1806 a grant was voted to the college for fifteen thousand pounds for the erection of a building for the care of the museum, and for a theatre for the delivery of public lectures on anatomy and surgery. A further sum of twelve thousand five hundred pounds was voted for the same object in 1810.

honor the memory of Hunter by reciting his merits as a man of genius, a discoverer, and an original investigator, it should be rendered especially contributory to the advancement and glory of surgery by showing what surgery really is, what underlies its study, and how it may be best cultivated to subserve the interests of humanity and of science. In glancing at the long list of Fellows of the college who have been intrusted with this honorable office from its establishment in 1814 to the present time, not a solitary name appears that is not creditably associated with the progress of surgery, while not a few of them occupied the highest position attainable in our profession. In 1877 and in 1879 this duty was discharged, respectively, by Sir James Paget and Professor George Murray Humphry, than whom Hunter has had no more worthy successors, or English surgery more able thinkers or more active workers.

With only three exceptions there has been no break in the delivery of the oration since it went into operation; but in 1850 the council of the college passed a resolution that the oration thenceforth should be delivered only every second year, it being regarded as "a hopeless task to seek for something new every year on so limited a subject."

By constant additions the Hunterian Museum now forms the most enormous collection of anatomical, surgical, and zoological preparations in the world. The only approach to it is the Dupuytren Museum at Paris, which, however, is chiefly a collection of pathological specimens. The collection of Hunter at the time of his decease embraced nearly fourteen thousand preparations, wet and dry, besides numerous shells and fossils. Every specimen was accompanied, when practicable, by a brief account of the case from which it was obtained, if it was a morbid one; or by an opinion of the animal, bird, reptile, or insect, if it was new to him.¹ The museum as at present constituted is especially rich in specimens of ethnology and comparative anatomy. One is also struck in passing through this vast Golgotha with the immense number of human urinary and biliary calculi, as well as intestinal concretions, and calculi from the inferior animals. Only recently the museum was enriched by a series of the most beautiful and valuable dissections, in the form of wet preparations, arranged in bottles, of the muscles, blood-vessels, and nerves of the human body, the work of a trained museum hand, not a medical man, begun by Dr. James Bell Pettigrew, and carried on under the supervision of Professor Flower, the present very intelligent, popular, and distinguished curator. Large as is the edifice in which the museum is contained, it will soon be too small for the purpose for which it was erected. It is highly creditable to the surgical profession of England that every member of it takes a deep personal interest in the subject, and closely identifies himself with its prosperity. No labor or expense is spared to extend its growth and to promote its usefulness. Annexed to this enormous collection of objects of anatomy, surgery, and natural history, is the library of the Royal College of Surgeons, now numbering nearly thirty-eight thousand volumes, or nearly fifteen thousand separate works, embracing copies of all the works of the fathers of the profession, and thirty-nine thousand tracts, pamphlets, essays, reports, and theses. Hunter himself had no library in the true sense of the term. He read little, and had no great respect for other men's writ-

ings or opinions. Nevertheless, he was always scrupulously honest in awarding in his writings and published papers to every man his dues; in other words, he never claimed or appropriated what was not his own. His pupils had often to tell him that such and such a discovery had been made before.

The executors of Hunter were Dr. Matthew Baillie² and Sir Everard Home, the one his nephew on his sister's side, and the other his brother-in-law. To the latter alone, however, was confided the care of his MSS., covering now fewer than twenty folio volumes, with the express injunction that he should prepare a catalogue of the museum, without which it would be comparatively valueless. These precious papers were sent to Home in 1800 by Mr. Clift, the conservator of the museum, and for a short time one of Mr. Hunter's most valued assistants. Instead of carrying out the wishes of the testator, Home, it is asserted, appropriated his MSS. to his own use, and, in 1823, threw them into the chimney of his study, the flame thus kindled being, according to his own confession, so great and alarming as to call out the fire-engines! The papers embraced not only what Hunter had written on comparative and pathological anatomy, but also his lectures on surgery; everything, in fact, but the museum itself.³ During the twenty-three years that Home retained these MSS. he contributed a greater number of papers to the Royal Society than any other Fellow of that distinguished body, besides publishing an elaborate work on comparative anatomy, most of which had, it is alleged, been purloined, at least substantially, from Hunter's portly volumes. It is hard to believe that such a theft could have been perpetrated by any rational being, and yet such would seem to have been the fact. Possibly, however, its atrocity may, after all, not have been so great as it is generally believed to have been. Sir James Paget, in his admirable Hunterian oration for 1877, expresses the belief that, through the care and fidelity of Mr. Clift, the MSS. had been, in great degree, utilized to Hunter's advantage before they were committed to the flames.⁴

RECENT PROGRESS IN FORENSIC MEDICINE.

BY F. W. DRAPER, M. D.

THE MEDICO-LEGAL VALUE OF SUBPLEURAL ECCHYMOSES.

SINCE Tardieu, in 1855, declared that "sanguineous extravasations scattered under the pleura, under the pericardium, and under the scalp, in whatever degree, and however few in number," were the specific lesions

² Dr. Baillie was the most popular and distinguished physician of his day in England. He was a pupil of his uncle, Dr. William Hunter, a brother of Joanna Baillie, the authoress, and the last medical man in London who carried the celebrated gold-headed cane, now in the possession of the Royal College of Physicians. In 1793 he published his celebrated work on Morbid Anatomy, for a long time the only treatise on the subject in the English language.

³ In burning these MSS. Home asserted that he had simply acted in accordance with his brother-in-law's injunctions. I cannot, however, find any reference to this subject in Hunter's will, and as he died very suddenly and unexpectedly it is not very probable that any such instruction was ever delivered.

⁴ Mr. Clift was the first curator of the museum, and served in that capacity upwards of forty years. In speaking of Hunter's papers Paget remarks: "All that was most important in the manuscripts is now published, the greater part by Mr. Owen in the *Essays and Observations*, and in his *Physiological Catalogue of the College Museum*. Whatever related in any way to the Hunterian specimens of morbid anatomy is printed in my *Pathological Catalogue*. The notes of the lectures are lost, and so also are some observations on surgery; but, on the whole," adds Paget, "I think that nearly all that was of great value was saved through Clift's fidelity."

¹ Henry Clive, Hunterian Oration for 1816. Adams's Life, p. 262.

of death by suffocation, subpleural ecchymoses have been studied attentively by medical jurists. For a long time, in France and elsewhere, Tardieu's statement was accepted; but it has not escaped criticism and denial. One of the most recent expressions of a feeling of doubt concerning the significance of the appearance alluded to is found in the record of the International Congress of Legal Medicine, in Paris, in 1878, wherein the following conclusion was reached and formally adopted: "Subpleural ecchymoses, which have been given as an indubitable sign of death by suffocation, cannot have, by themselves considered, any value in legal medicine, the causes which can produce them being very varied."

In an elaborate review of the subject, undertaken in consequence of these later criticisms, A. Henocque has given a valuable contribution to our knowledge of these minute extravasations.¹ Granting that it is in death by suffocation that we find these lesions most constantly, the author remarks that instances have been recorded of death by this cause wherein the ecchymoses were not found; and, on the other hand, many cases have been observed in which, after death from causes other than suffocation, the appearances in question were fully developed. In this latter class are included various forms of violent death, as, for example, death by poison (phosphorus, arsenic, mercury, strychnia, etc.), by drowning, hanging, and strangulation, by chloroform and charcoal vapor. But it is not alone in death by violence that the ecchymoses are manifested: they have been observed in cerebral and spinal affections, in eclampsia and epilepsy, tetanus, cerebral hemorrhage, meningitis, and sunstroke; in croup and diphtheria, whooping-cough, pneumonia, and suffocative catarrh; in diseases of the heart; and, in infancy especially, in bronchitis, lobular pneumonia, and the pleuro-pulmonary complications of measles and diphtheria.

Henocque insists that the older authors were not sufficiently exact in their description of the lesions referred to. He says: "One ought to consider as subpleural ecchymoses those extravasations of blood recalling the spots of purpura, punctate, rounded, or scalloped, which, situated under the pleura, are easily distinguished from lesions of the pulmonary parenchyma." Histologically, they consist of a mass of red globules, crowded together, forming a small disk, with its edges ill defined, developed under the pleura, and not penetrating into the pulmonary lobules; they seem to disappear when the lung is decomposed or dried, but insufflation restores their original appearance, if care is taken not to do the operation too vigorously; they are anatomical lesions due to the rupture of the capillaries situated at the periphery of the lobules under the pleura, and are to be distinguished from the larger hemorrhages which accompany apoplectic nodules, emphysema, and pulmonary edema.

General physiology has lately shown us the subpleural ecchymoses under a new aspect. Brown-Séquard has demonstrated the production of ecchymoses and of effusions of blood into the lungs in consequence of a lesion of certain parts of the brain; wounds of the pons Varolii in the vicinity of the insertion of the peduncles of the cerebellum quickly produce them.

In the presence of all these facts it is necessary to give to this sign a limited value in legal medicine; the more so since it is invoked precisely in cases where one

wishes to distinguish by means of it the various causes of death supposed to be violent, such as suffocation of the new-born, hanging, and drowning; and it is in these circumstances especially that the subpleural ecchymoses are, by themselves, an insufficient proof, because it is always open to question. The practical point is that it will always be necessary, at the same time that one notes their presence, to take account of all the conditions which can produce them, and to indicate with care the presence or the absence of cerebral or pulmonary lesions.

As to the mechanism of the production of the ecchymoses under the pleura, Henocque adopts the respiratory theory in preference to the "circulatory" theory of Tardieu, founded on the arrest or decrease of cardiac activity, or the vaso-motor theory of Brown-Séquard. The respiratory efforts, he believes, exercise on the pulmonary capillaries a force which is favored by the peculiar anatomical structure of the pulmonary arterioles, their numerous flexuosities, their larger calibre, their more direct anastomoses, their more open net-work as compared with the capillaries; while the minute pulmonary veins are characterized, on the other hand, by a predominance of circular fibres in their walls, rendering their contractions more active and quicker than is possible in other parts of the venous system.

THE RATE OF COOLING OF THE HUMAN BODY AFTER DEATH.

Dr. J. Wilkie Burman has recorded the results of an interesting series of observations which he has conducted with evident care.² The following are his conclusions: "The mean average rate of cooling of seven dead bodies, all under fairly similar conditions as to external circumstances, was $1\frac{1}{3}^{\circ}$ F. per hour, the minimum rate being $1\frac{1}{5}^{\circ}$ F., and the maximum being $2\frac{1}{5}^{\circ}$ F. In two of the cases, where the temperature at the time of death was unusually high, there was a considerably greater amount of cooling during the first hour after death than in the other cases, the average rate of cooling during that time in the two cases being $4\frac{1}{2}^{\circ}$ F."

Upon the assumption that, as a rule (according to Goodhart), we should be pretty accurate in estimating the temperature at the time of death in a body found dead to have been $98\frac{3}{4}^{\circ}$ F., the practical conclusion of Burman's observations is, as he remarks, that, "given a body found dead in bed, in a room with a temperature ranging from 50° to 70° F., with ordinary bedding, we may fairly estimate the time of death by taking the temperature of the axilla, the difference between which and the average normal temperature (98.4° F.) divided by $1\frac{1}{3}$ would give us, approximately, the number of hours since the death."

Dr. Burman gives full details of his observations in various tables and in a chart. The dead bodies, upon which the temperature was studied, were those of adult male patients dying in a lunatic asylum. The thermometer was kept in position in the axilla through an average period of thirteen hours, and its record was noted at intervals of an hour each.

IMPOTENCE AND STERILITY IN THE MALE.

Dr. S. W. Gross³ considers these forms of sexual disability as a not uncommon result of a reflex neuro-

¹ *Gazette hebdomadaire*, xvii. Nos. 1, 2, and 3. 1880.

² *Edinburgh Medical Journal*, May, 1880, page 993.

³ *Medical News and Abstract*, September, 1880.

sis arising from inflammatory affections of the reproductive apparatus. He has found that the nervous aberration here alluded to is usually traceable to inflammatory disorders of the prostate, "which bear the same relation to nervous affections in the male that lesions of the uterus do to allied disorders in the opposite sex. The prostate, with its intercalated acinous glands and the structures that are contained within it and that traverse it, as the urethra, the veru montanum, the sinus pocularis, or prostatic ducts, or utricle (which is the homologue of the uterus), and the ejaculatory ducts, are supplied by large nerves derived from the hypogastric plexus of the sympathetic, the sacral plexus of the spinal nerves, and, through the lumbosacral trunk, from the lumbar plexus. In consequence of the free interchange of fibres between the sympathetic and the cerebro-spinal systems of nerves, it is obvious that the component parts of the genitalia are not only in intimate connection with one another, but, also, through the agency of the cord, with remote parts."

The result of this close nervous alliance and of the consequent ready reflex influence of prostatic disease is that in some cases (and this is the most common form of sexual debility) intercourse is possible, though unsatisfactory on account of imperfect or feeble erection and premature ejaculation. In these subjects the exciting cause of the disability will frequently be found to be a chronic hyperesthesia and inflammation of the prostatic urethra. In another class of cases the same morbid sensibility of the prostatic urethra results in entire loss of the power of erection, without, however, loss of sexual desire, so that men so affected are not only impotent, but sterile as well. In still other cases there is actual aspermatism.

The aetiological factor in the cases observed by Dr. Gross was gonorrhoea in more than two thirds of the patients, while in all but one of the remaining instances masturbation was the exciting cause. The undue sensibility of the prostatic urethra here described is readily determined by means of a bulbous exploratory bougie.

CASES OF MEDICO-LEGAL INTEREST.

M. Jalaguier reported the following case before the Anatomical Society of Paris.¹ On the 10th of December, a man received a blow in the right side from the blade of a sword-cane. He lost but little blood, and, believing himself but slightly wounded, he went home rather than to a hospital. Two days later he was admitted to Hôtel Dieu. The appearances at this time were so insignificant that M. Riehet concluded, after careful examination, that the wound had not penetrated the abdominal wall. On the third day after the assault the patient was nervous and restless, and delirium was observed at night. On the fourth day true delirium tremens developed, and this continued till the patient's death, on the eighth day after the injury.

The autopsy was made by Brouardel. The external wound was marked by a small, blackish triangular crust in the right flank. On the inner surface of the abdominal wall the peritonæum presented a red point marking the passage of the weapon. The sword penetrated the liver, entering at the transverse fissure, and emerging on the upper surface two cm. behind the anterior border. There was a wound of the diaphragm, four cm. in front of the opening for the in-

ferior vena cava. In the posterior mediastinum was a large ecchymosis. The weapon entered the heart through the posterior wall of the left ventricle, traversed the cavity of this ventricle, and entered the anterior pillar of the mitral valve (columnæ carnea), which it penetrated to the depth of eight mm., the cavity of the wound being filled with a fibrinous clot, pyramidal in shape, with its base measuring three mm. at the endocardial surface. The total length of the wound, from the point of entrance to its termination in the anterior wall of the left ventricle, was twenty-three cm. (nine inches). The cavity of the peritonæum and that of the pericardium were filled with fluid blood. There was no sign of inflammation in any part, and all the organs were healthy.

M. Jalaguier remarks that without doubt data are not wanting to prove that persons have survived for eight or ten days after a wound of the heart when the weapon was small and sharp. Statistics show that a wound of the left ventricle is oftener immediately fatal than a wound of the right ventricle. As to the immediate cause of the hæmorrhage into the pericardium, Jalaguier suggests that a clot had originally plugged the wound, but this clot in the course of its reabsorption had been expelled.

The investigation of this case raised a delicate medico-legal question: Was death caused by the wound or by delirium tremens? Or, in other words, if the patient had not been under the influence of alcohol, would he have recovered? "One might answer that cicatrization has been observed in wounds of the heart by sharp-pointed instruments. But here a new difficulty arises: it is very plain that the wound, all question of its gravity aside, by the single fact that it was a wound, sufficed to initiate the delirium tremens, so that the death was the result of the reciprocal and consecutive action of the traumatism on the alcoholic temperament, and finally of this on the wound." Professor Brouardel, in his medico-legal report, stated among his conclusions as follows:—

"The death of G. was in consequence of the wound of the heart.

"The access of the delirium tremens determined a pulmonary congestion, which had as a result an increase of pressure in the circulatory apparatus. At the same time and by the same cause the blood became more fluid. These conditions rendered unavailing the resistance to hæmorrhage by temporary clots and blood escaped into the pericardial and peritoneal cavities.

"The death, then, was the result of hæmorrhage supervening in the last hours of life, and having as its cause the wound of the heart and that of the liver. These wounds might have cicatrized if G. had not had alcoholic habits, which promoted an outbreak of delirium tremens."

With the foregoing case, mention may properly be made of an instance reported by Dr. M. M. Robbins, of Aurora, Ill.² In this case there was a perforating pistol-shot wound of the anterior wall of the left ventricle of the heart, the patient surviving till the eleventh day, when he succumbed suddenly. This man had been hit by a pistol-ball (thirty-two calibre), which had passed through the left arm and had penetrated the cavity of the chest through the fourth intercostal space, a little inside the nipple-line. Immediately after the shot the man ran about fifty feet; he

¹ Le Progrès médical, No. 32, 1880, page 649

² The Medical Record, November 22, 1880, page 599.

fell presently into a condition of shock, but reaction occurred satisfactorily, and on the ninth day the patient was out-of-doors. He had no pain or other symptom to indicate that any vital organ had been injured. On the eleventh day he walked about a while in the morning; later he took a short ride in an easy carriage, and, on his return, said that he felt better than at any time since the shot was received. During the rest of the day he was quiet. Immediately after eating a light supper he complained of a severe pain and pressure in the cardiac region, and in a few minutes was dead.

At the autopsy the pericardium was found filled with blood, and there was a "considerable quantity" of blood in the left pleural cavity. The ball had struck the upper border of the fifth rib, perforated the pericardium, struck the left ventricle on its anterior wall, passed into and through the ventricular cavity, and lodged in the posterior wall, penetrating nearly to the external surface. At this point in the posterior wall there was a stellate rupture at the apex of a slight elevation whose wall was very thin. It is possible that this wall was rendered thinner by the action of the roughened surface of the bullet after its lodgment. One of the pillars of the columnæ carneæ was directly over the point where the ball entered the left ventricle, and may have prevented or helped to prevent the flow of blood through the anterior wound.

Hospital Practice and Clinical Memoranda.

CASES OF PNEUMONIA.¹

BY WILLIAM F. BOLLES, M. D.

CASE I. I was called, July 13th, to see a delicate little girl of about five years, who had been as well as usual since having scarlatina the year before, excepting a cough lingering after pertussis in the winter. The day before my visit she seemed as well as usual, and had been playing out in the hot sun, as she also had on previous days. When attacked she vomited, and lay still and listless upon the lounge, complaining of headache. She was flushed and hot, but gave no indication of any local trouble. The attack being regarded as one of mild heat fever, ordinary refrigerants and quiet were directed. She rapidly recovered, and was not seen by her attendant again for a week, when a prominence of the right clavicle attracted the mother's attention. She had been nearly but not quite well in the mean time, and had become a little emaciated. There was a considerable swelling of the upper part of the right chest, chiefly due to the sternal end of the clavicle, which was pushed forward. There was no redness or edema over it, and it was but slightly tender. The veins around and over it were large and blue. A flaxseed poultice was applied, and in a few days more a suppurating gland (?) rose from behind the inner end of the right clavicle, and was opened. In eight or ten days more — August 2d — she went with her parents to Swampscott, but while about house and even out-of-doors for a few days before, on the day of starting she was not quite so well, and wanted her father to carry her the short distance they had to walk to the cars. She had had some cough, which had been worse for a

few days. During the first day at Swampscott she became worse, and on the second and third days still more sick, when I went down to see her. She had scarcely been up since her arrival, and for the last two days had lain abed all the time, hot, dry, and dull, with a hard, frequent cough, and little or no expectoration. Temperature 103° F., pulse 120 to 140. The appetite was gone, and she looked somewhat more emaciated. The granulations in the neck, about half an inch deep, were a little oedematous; the blue veins on the body and limbs seemed to show plainer.

There were dullness and bronchial respiration, with bronchophony and fine râles in the upper five centimeters of the right lung; other parts of both lungs clear.

On being brought home from the shore she immediately began to improve, and in about three weeks was entirely well. An examination made three months later shows that the recovery is perfect. There is a little harshness of respiration, probably of a cicatricial character, at the right apex.

This was a case likely to awaken the gravest apprehension in regard to its result. The delicate habit of the child, the dullness and râles at the apex, the cough, wasting, and fever, the blue veins and abscess, with phthisis hereditary, certainly excused her attendant at Swampscott, especially if the fingers were clubbed and the two sides of the chest different, as they seemed to him to be, in considering it a case of that disease. I relied upon the sudden indisposition of July 13th, which was undoubtedly the beginning of the abscess, upon her fair health up to that time, in spite of the cough, and upon the very rapid course of her sickness during the three or four days of her stay at the beach, to consider it an acute inflammation set up by the abscess and secondary to it, passing across the pleura by contiguity, and the result has confirmed my diagnosis.

CASE II. Of the following case I have lost my notes, but as it was deeply impressed upon my memory, and I had already reported it before another society, I think by the aid of dates of visits, etc., I can give a reasonably accurate account of it in a narrative form. The patient was a store-house keeper, twenty-nine years old, and married. There was no consumptive taint in his family that I could discover, and up to a certain date he was perfectly well. That date was the 17th of June, 1875. Either on this day or evening, after watching the procession, he became very chilly, and had what he described as a terrible cold, with hard cough, pain in the left side, and a good deal of fever. He had no physician then, however; was, I think, laid up for a few days, but did not go to bed, and afterwards resumed his work. As the cough did not abate, he got some transient medical advice of an unknown physician, but had no examination of the chest. When he came to me, nine or ten weeks later, he had lost flesh, was sweating at night, had a loud and hard cough, and felt weak, but still had had no thought of giving up business. His appetite and courage were good, and he protested that there was nothing the matter with him but a cold.

I was surprised to find his temperature 102° F. (his pulse was about 100, but that was to be expected), and still more so to find, upon examining his chest the signs of pneumonia in the lower lobe of the left lung, — in the stage of resolution, — dullness and coarse râles; no trouble elsewhere. His night-sweats disap-

¹ Read before the Boston Society for Medical Improvement, January 24, 1881.

peared under the use of ergot. He improved for a year, worked at his business most of the winter, went to the mountains in the summer, was better the next fall, failed the next spring, and died about two years from the time when I first saw him, after breaking down in both lungs and frightful hæmorrhages.

This would have been far more conclusive as an instance of lobar pneumonia eventuating in a chronic form, had I or some one seen him at the start and properly examined his lungs; but the history of previous health and sudden invasion after exposure, without predisposition to tuberculosis, was so positive that I am inclined to regard it as such. On the other hand, the extreme rarity of an inflammation of one entire lobe existing as an acute attack and allowing the patient to continue out of bed bears strongly against it, and it is not impossible that a catarrhal form existed from the first. Its origin in the lower lobe would be remarkable even in this case.

CASE III. A young married grocer first sent for me June 20th, having a day or two before had chills followed by very quick pulse and moderately elevated temperature. He had some cough, the cheeks were flushed as in pneumonia, the urine was diminished and dark, but his respirations were not more than 20 per minute, full and deep; the chest expanded and contracted perfectly, gave an exaggerated and tympanitic resonance everywhere, and the respiratory murmurs were everywhere full, — a little puerile, — perhaps, but if he had appeared well I should have declared the lungs to be sound. He was far from well, though, and when I was first called had fallen into a state of collapse, which had alarmed his family and previous attendant into the belief that he was dying. From this gentleman I learned that he had had a cough, regarded by him as bronchitis, for six or eight weeks, but he had been always to his business, and never had any elevation of temperature. He had examined the lungs on the day before with the same negative result as myself and also examined them with me. It seemed to us both that the patient would die in a day or two, and that he probably had miliary tubercles.

On the fifth day, the third of my attendance, I wrote that "the patient was restless, groaning and tossing on account of flatulence and distress in the stomach" (he was always dyspeptic, and had more or less trouble of this kind, and it followed him through his sickness, requiring frequent medical interference). "There is a spot of bronchial respiration and bronchophony, not very well marked, at the inner border of the left scapula." In the afternoon he was less troubled with flatulence, slept comfortably, and seemed better.

Next day there was slight dullness at the affected spot, and the signs above noted were more marked. And again, on the day following, râles could be heard over most of this side, behind, with slight dullness and some degree of bronchial respiration and bronchophony; not enough to hide, however, the spot first attacked, which presented evidence of complete solidification in the most typical manner. Occasional râles were heard upon the right.

On the third day after his chills (my first day) his temperature was about 103° F., and rose on the fifth to 103.5° F.; then it began to drop, and on the twelfth day reached 99° F. The pulse, starting at the same time at 136, reached 80 on the ninth day, and then began to rise again. The respirations were remarkable. When the pulse was 136 and the temperature 103° F.

they were only 29; gradually rose in five days to an average of 30, and reached 20 again on the nineteenth day. He improved, as if getting over a lung fever, and had the appearance of convalescence at about this time.

On the twelfth day the following record was made: "There is slight dullness of the left front, with exaggerated respiratory murmur; no râles in front. Respiration and resonance of right side normal;" the tympanitic resonance noticed at first has disappeared. Râles and dullness in the middle left scapular region, as before; dullness doubtful below.

Fourteenth day. Back clearing; a little spot of solidification, with a few râles around left nipple (corresponding to the one in the back).

Then a little more trouble invaded the left base and left it again. On the whole, the lung seemed to be clearing, but the spot which first appeared never disappeared, now becoming larger, and again smaller, but always solid. On the thirty-sixth day, for instance, "a spot as large as the palm of the hand around the left nipple and a corresponding space behind were solidified; the apex was clear, and but few râles, with moderate dullness, were left below; nothing upon the right." The temperature and pulse were each about 100; the respirations not above 25, generally below. He got better, and out in the fall. The temperature kept most of the time below 100° F. The cough and greenish and thick expectoration continued. He gained some flesh, at one time, but the lungs never cleared any more, nor changed much, while I saw him. The winter was spent in Georgia, from whence he returned the next June to die.

This case I do not regard as one of ordinary pneumonia, resulting in the chronic form, but rather as chronic pneumonia from the first, beginning long before he was taken to bed; quiet at first, but developed by an intercurrent acute attack. I had neglected to say that there was a moderate phthisical tendency in the family. The previous history of cough, however, was not prominent, nor was the cough the warning lacking of tuberculosis. A well-developed cold, resulting from exposure in the spring, was regarded as its origin. The irregular manner in which the pneumonia advanced, the disproportion between the amount of lung involved and the symptoms, together with its peculiar position at all times, prevented a favorable prognosis; yet at the end of ten days the only suspicious sign was the slowness of the respirations, and their rise in frequency as the pulse and temperature fell.

CASE IV. Mr. M., a young man of twenty years, of excellent general health, by occupation a clerk, took cold a week before sending for me, but continued up and about, and went to church, even, two days before; in the afternoon, after returning from church, he walked out without an overcoat. On the next day he had chilly feelings, but no decided chill, followed by pain in the left side, for which he took a "rum sweat" in the evening, in vain.

When I first saw him he was up and dressed, but feverish, with flushed face and steady cough. He complained moderately of the pain in his side, which was a dull ache; the expectoration was rusty and not abundant; the pulse was high, but not recorded; the temperature 104° F. Dullness and bronchial respiration were to be heard over the lower lobe of the left lung. (Quinine.) The patient was an only son of indulgent parents, unaccustomed to self-restraint, nervous, excit-

able, and willful, — on the whole, the most uncomfortable and unreconciled person of adult years that I have ever seen; but the disease seemed perfectly simple. I wrote that evening in my memorandum book, "I have seen to-day a case of pneumonia remarkable for being exactly typical [having previously had a number of irregular and very serious cases, this seemed to me worth noting]: every symptom is present in about its proper intensity; there is nothing absent which would be expected in a model case, and nothing present which would not be."

For the next two or three days he seemed moderately sick, very restless and uneasy, with bronchia-respiration, dullness, and bronchophony, rusty expectoration and pain, much as at first; râles few and not prominent. — at first, none. Temperature 104° F., pulse 120, respiration 30.

On the sixth day from the chill, when all seemed to be going on well, he had a sharp attack of pleuritic pain, lasting all the following night and into the next day, accompanied with a slight rise in the temperature and pulse, which had gone down several numbers, and a great rise in respiration to 40 per minute. So far during his sickness he had been so cross and impatient, so restless and obstinate in throwing off the clothes and stripping himself generally, that, although three persons were in constant attendance upon him, we all thought that he had taken cold from exposure. He was not still a minute, but panted, coughed, tossed, and scolded the entire time.

Next day, the eighth, he became quieter, and slept considerable; could lie upon the right side previously only upon the back.

On the ninth day there was pain in the lower part of the right side. Examination showed roughened respiratory sounds throughout the right lung, with occasional coarse râles; broncho-vesicular respiration, friction sound, and slight dullness at the base, back, and side. Râles abundant everywhere in the left side, back, and front, excepting at the apex. They were coarse and clearing below; finer, with bronchophony in the middle portion of the back, where the dullness was most marked. Below there was more resonance than at time of previous examinations; moderately dull in front. Thus, as was to be expected, the lobe first attacked was already in process of resolution; but the trouble had advanced into the upper lobe on the left, which was partly solidified, and made a slight attack upon the lower part of the right. There had been local inflammations of both pleurae, but no evidence of effusion into either.

On the tenth and eleventh days defervescence took place, and, in spite of the active condition of the disease in the middle of the left lung, the temperature dropped on the eleventh day to 98.4° F., the pulse to 92. The respiration kept up above 40. Although uncomfortable and nervous, he appeared to be convalescent.

On the twelfth day he was examined, the result confirming entirely that of the ninth; but as this state of the lung lasted a considerable time and was a source of great anxiety before the end of the case, I will read it once more: There is dullness of the entire left back; clearing below, with broncho-vesicular respiration; in the lower scapular region intensely dull; bronchial respiration with fine râles marked; above less dull; respiration partly vesicular; the abnormal sounds of the right side have partly disappeared.

For several days there was very little change; he

had a little pain all the time in the left side, sweat considerably at times, and was, as usual, restless and irritable. The cough was not, after the first five or six days, excessive; after the first week it diminished notably, and by the end of the second there was very little; the expectoration, too, was scant, or none.

Twentieth day. Short, dry, irritating cough.

Twenty-first. Comfortable; vomited.

On the twenty-second day there was no change in the sounds of the left back from those of the twelfth. The front was becoming more dull; there were a few râles again at the extreme base of the right. He appeared somewhat better, and the tongue, which at first had been heavily coated, was quite clean; his appetite (for milk and liquids) had so far been very good. The urine, which had been high colored and scanty at first, but later quite normal, suddenly became very bloody, with disseminated corpuscles and albumen; it was so red as to be opaque in a four-ounce phial. There is and has been at times pain in the lower part of the right side; expectoration streaked with blood, not abundant; sputa mucous, very tenacious, clear, white.

Twenty-fifth day. Almost no change in the left lung; slight friction at base of right. (Dr. Edes in consultation.) The left front is becoming duller; tubular respiration and râles have advanced almost to the very top; scarcely any sounds can be heard in the middle of this lung, either in front or behind, in consequence of the almost complete absence of respiratory movement on this side. The scapular region is almost flat, and the voice sound approaches egophony; right base still dull, with diminished respiration. The appetite has completely disappeared; he feels full and bloated; vomits. Urine still red. Dyspeptic, dull, and depressed.

Twenty-seventh day. Vomited. (Dr. Edes again.) The most intense dullness and bronchial respiration now are from the apex down along the sternal half of the chest; in front and the middle of the back coarse and gurgling sounds; elsewhere in front lower, and median regions behind clearer. The patient, who had begun to sit up ten days ago in a chair, has not been up for a week, is pale and cachectic, takes no solid food, and strenuously objects to liquids.

Twenty-eighth day. Urine becoming clearer. Ate a little breakfast.

Upon the thirtieth day pain appeared near the right saphenous opening, increasing by the next day to a high degree of severity, extending down to the calf, which is about as tender as the groin, and up along the right side. The leg was drawn up, and the slightest motion caused excruciating agony; when perfectly quiet it was sometimes comparatively comfortable. The tongue became dry on account of his panting and groaning, and the respiration rose to 48 per minute from the same cause. The leg was becoming oedematous. Vomited. There was still no sign of clearing in the middle part of the lung, which had been solidified nearly a month. The breath was offensive. The urine, which had cleared itself nearly of blood, then (thirty-fifth day) suddenly became red again, with increase of vomiting and complete absence of appetite. (Gallic acid given and discontinued). Patient very nervous, restless, and thirsty.

The fortieth day arrived, with no improvement, and all medicines and food by the stomach were given up, and he was to have nothing but egg and milk

injections, varied at times by brandy and beef tea; and this mode of feeding was continued for several days.

For nearly a month there had been very little expectoration. His cough, after the first week, with a few exceptions, was never excessive, and much of the time he would raise only half a dozen mucous sputa in the course of the day; but suddenly, on the night of the forty-first day, he began to cough violently, and continued for several hours, raising during this time fully four ounces of pure pus, creamy yellow and not tenacious. During the day following half as much more came up, and on successive days a still further quantity. The leg continued swollen and unmanageable, but less painful.

He was as savage as ever, and at one time refused to take anything in any way for a day, quarreled with his mother, and was so sullen that I doubted his entire sanity for a moment. Still, he appeared better, and on the forty-fifth day began to eat a little; on the next raised more pus, ate a fair supper, and went without injections; was bright and talkative.

I recorded an examination of his chest on the forty-eighth day. The right side was nearly normal. Left front, bronchial respiration at apex four fingers' breadth; broncho-vesicular with râles in the middle of the chest; very little sound below the nipple; resonance dull above and below, good in the middle, a little tympanic if anything under the third rib; behind the respiration was vesicular, with râles below, bronchial, and very much diminished beneath the scapula, with oërophony fairly marked above the middle; bronchial above. He coughed a good deal, and raised much pus during the night; urine but little bloody; appetite very good.

From this time forth it is hardly necessary to follow his improvement by daily records. He gained slowly and doubtfully for a while. There was another attack of bloody urine, with diminution of appetite, and a coughing spell upon the sixty-first day, during which he raised half a pint of pus; but in general he ate and slept well, gained every day a little, became cheerful and tractable, began to sit up about the fifty-fifth day, walked a little a week later, in which he was much hindered by his greatly swollen leg, and got out-of-doors in about three months. The left side is almost passive in respiration, has shrunk considerably, and the sounds therein are very much diminished. I made a number of careful examinations of the exact position and character of the abnormal sounds, which, if the case had proved fatal, would have made an autopsy exceedingly interesting, but as it is have no prospect of being tested. I visited him this morning, however, to make one further observation upon him. He is rapidly improving; walked a mile and back yesterday without fatigue; "could have walked five miles, only that his leg pained him a little." The whole leg is still slightly swollen; can run without getting much out of breath. Has had but very little cough for a fortnight. Feels well enough to return to business.

EXAMINATION: MEASUREMENTS.

Under the arm	78 to 82½	cc.
Each side right	42	"
" " left	39	"
Expansion, right	3	"
" left	0.5	"
At ensiform level	75.5 to 79.5	"
Expansion, right	2	"
" left	1	"
Each side right	42	"
" left	37	"

There are no râles to be heard anywhere. The respiratory sounds are not loud, and are rather sluggish, but not otherwise abnormal in the right side; in the left they are still more faint, and in the scapular region are scarcely to be heard above the general muffled roaring everywhere in the chest. The voice sound and resonance are good everywhere except in this space; the front has cleared remarkably.

This case, if I am not mistaken, began as a simple pneumonia, involving the lower lobe of the right lung, and following, so far as that lobe was concerned, at first the ordinary course, resolution beginning and the fever abating on the ninth or tenth day. Before this took place, however, an invasion of a slower and more destructive type of the disease had attacked the middle of the lung and ruined it; the left pleurisy was coincident with this advance, and probably a part of it, as the pain was referred to this location; from this point as a centre and source of irritation inflammation extended in all directions, gradually working up until the apex was reached, down in front to the base again, outward and inward as far as it could go, but not quite reaching the bottom of the back, then gradually receding a little as the active stage of the abscess passed by. The rupture of the abscess, its evacuation, and the collapse of the side were evident enough to need no comment. The repeated attacks of hæmaturia were undoubtedly due to successive infarctions in the kidney, resulting from thrombosis in the lung, and the thrombus in the femoral or iliac vein was a part of the same trouble. It is well worth considering whether the inflammation of the middle of the lung (or rather the lower part of the upper lobe), with all its consequences, was not due to the uncontrollable restlessness of the patient; if he had had a cellulitis of the leg, and had kept it constantly turning from side to side, or kicking in the air, he could not have treated it worse than he did his inflamed lung by the panting, grunting, scolding, and tossing of the first weeks of his illness.

There is, on the other hand, good reason for believing that there may have been a local empyæma, which broke into the lung; yet it must have been strictly confined, since before it broke there were resonance and respiratory sounds to be heard both above and below it. He spit up frequently streaks of blood during the few weeks previous to the discharges, and his breath was at times offensive, but the pus when it came was pretty pure at first, afterwards tenacious and mixed with sputa.

A chief point of interest in these last three cases to the writer, but one which can hardly be presented on paper, was the fact that at an early stage there was a very strong resemblance in the condition and appearance of the patients and the physical signs, although there were certainly two and perhaps three quite distinct diseases.

— (Scene: office in Dublin Life Insurance.) Surgeon of the company: Heart and liver sound as a bell. Be Garge, ye've the finest life I ever saw, sor! What's your business or profession now?" Applicant: "I have n't got any." Surgeon: Fwhat! ye don't mean to say ye've got land?" Applicant: "A few acres." Surgeon: "Faith, thin, I'm sorry for ye, but ye won't do for us!" (Certificate refused.) — *Punch*.

A CASE OF GUMMOUS INFILTRATION OF THE INGUINAL GLANDS, FOLLOWED BY A PUSTULO-CRUSTACEOUS SYPHILIDE.

BY F. R. STURGIS, M. D.,

Clinical Professor of Venereal Diseases in the Medical Department of the University of the City of New York, etc., etc.

THE case I am about to relate is of special interest in several ways, and in none more than in showing how easily the glandular and peri-glandular enlargements in the late stages of syphilis may be mistaken for ordinary buboes and attributed to other than to their true cause. Nor is this of importance solely from a diagnostic point, for the treatment of the two varieties of bubo is entirely different, and what would answer for one would not for the other.

On December 13, 1879, I was consulted by a gentleman for a swelling in the right groin, which had lasted for a few days, and which had, so far as he could give me any history of his case, come on without injury. Upon examination, I found in the right groin a swelling 2" in length and about 3/4" in breadth, tense and brawny to the touch, without any appreciable redness, and presenting no fluctuation; no pain was complained of. This swelling seemed to be composed of an infiltration of some sort into the glandular and peri-glandular tissues of the part, which matted them firmly together and prevented the component parts from being distinguished from each other. Some limping of the gait was apparent, due less to pain than to mechanical impediment from size. A few days later a similar but smaller swelling came on in the left groin.

This condition of affairs puzzled me exceedingly; I was disposed to suspect something more than an idiopathic adenitis, and yet the patient strongly denied any syphilitic antecedents. The only thing to do was to await developments. Tincture of iodine was applied to the bubo once every day, which diminished the pain, but did not reduce the swelling.

He then left town for a short time, returning again on the first day of January, 1880, as badly off as, if not worse than, when he went away. During his absence the swelling had again become painful, and, worse than all, in the centre of each bubo was a spot of softened, broken-down tissue. Again a careful examination failed to reveal any vestige of present venereal disease, such as a simple venereal ulcer, or an urethritis, and the history gave me no account of an injury. What was to be done? Open the buboes? I could not divest my mind of the idea that these buboes did not contain pus, and I therefore determined to await further developments. The patient meantime was losing flesh and strength, and his mental excitement was but too plainly shown in his face. Iodine was still applied locally and a ferruginous tonic was given internally.

Matters remained stationary until January 6, 1880, when he appeared one day with a pustular eruption on his legs. This eruption began, he told me, as round hard lumps under the skin, which rapidly pushed forward and became crowned with a pustule. These speedily broke down and were covered with crusts, in which condition I saw them three days later, that is, on January 9, 1880. There was now no longer room for doubt in my mind. A case of syphilis of the pustulo-crustaceous kind stared me in the face, and the buboes were fine examples of gummosus infiltrations of glands. I then modified my previous treatment. The ferruginous tonic was discontinued, the iodide of potas-
ium

was substituted in ten-grain doses thrice daily, to begin with, and the iodine locally was continued. For the next ten days the pustules appeared rapidly from his ankles up to his waist; these pustules ulcerated and became crusted, so that on January 16th there were on the lower portion of his body a dozen scabs, and that in spite of the gradual increase of the iodide up to twenty grains thrice daily. The iodine was discontinued after a few days' use, and one half drachm of a twenty per cent. ointment of the oleate of mercury was then substituted, to be rubbed into the groins. The iodide was steadily pushed to a point where the patient was taking fifty grains three times daily, with the intunction of half a drachm of the oleate of mercury at night. In the mean time, before this amount had been reached, the inguinal enlargements were reduced in size, and the softened central spot had not opened. The pustulo-crustaceous eruption was quite slow at first in coming under the influence of treatment, but when once this was established they also disappeared favorably. After the oleate had been used for some time it was discontinued, and on February 10th the following changes in the treatment instituted: the iodide of potassium was given twice daily in fifty-grain doses well diluted with water, after eating; and at midday, also after eating, one half grain of the protiodide of mercury in pill form was given. As soon as the pill was substituted for the third dose of the iodide the improvement in the eruption was very marked. This eruption, on disappearing after the dropping off of the crust, left a deep purple stain behind it which gradually faded away, to give place to a white, depressed cicatrix.

It must not be supposed that this eruption, detailed above, was the only one which appeared. On the contrary, from time to time, fresh pustules have sprung up, but these have shown little tendency to ulcerate, and have speedily dried up. They were for the most part confined to the legs and buttocks; a few of them, however, have come upon the face, especially upon the forehead.

The generally condition of the patient was at first very poor and very feeble; as the specific treatment began to get the upper hand of the disease, he rallied, and finally it was pleasing to note that as his system came more and more under the influence of the medicines the gain in health and strength was rapid and marked.

In questioning him again with regard to any previous history of syphilis I failed to elicit anything definite or of value about the past. He was an intelligent and an educated man, without the slightest desire for concealment or evasion; indeed, he was most solicitous about his condition, and very anxious to give me any aid he could to arrive at a correct diagnosis. Yet he was able to give me nothing in the slightest degree trustworthy, and the diagnosis had therefore to be made from present indications, and without any regard to previous histories.

In this case there are several points of interest, — namely, many of importance, — upon which the correctness of the diagnosis may depend, and to which I desire particularly to call attention. The first is the appearance of the adenitis, unattended by any symptoms which would serve to assist in forming the diagnosis. There is no definite history of previous syphilis; there is no present urethritis, nor ulceration, either declared or concealed, to assist in forming an opinion; the sur-

geon is brought face to face with a bunch of glands which are brawny and matted together, resembling more than anything else the glandular inflammation concomitant with the chaneroid, and yet with no chaneroid discoverable to give it a plea for existence. And then, as if to add still further to the uncertainty, this swelling begins to show a soft spot, apparently threatening suppuration. Nor does the character of the pain give a clew. In this case, although present, it was not acute, but of a dull, heavy character, and the bubo itself was not accompanied by redness nor any inflammatory symptom; in fact, it did not differ from that variety of abscess known as the cold abscess, the *abcès à froid* of the French, and which sometimes occurs in glandular as well as cellular tissue. Yet with all these circumstances pointing to the bubo as being one of spontaneous and idiopathic origin, and perhaps requiring incision, I could not make up my mind to do so, nor could I divest myself of the idea that it was due to syphilis. Fortunately my patient was a sensible man; I told him my suspicions, and strongly advised an expectant treatment for a short time. The wisdom of the advice was apparent as soon as the pustulo-crustaceous eruption appeared, for had the buboes been opened the result would have been a long tedious necrosis of the gland and an ugly cicatrix.

As soon as the pu-tules broke out the absence of any syphilitic history was of comparatively little importance, inasmuch as I believe that a pustular eruption occurring in an ordinary healthy adult, say, between the ages of twenty and forty-five, is ninety-nine times in a hundred due to syphilis, and will yield to anti-syphilitic treatment; hence the moment these pustules appeared my mind was made up as to their nature, and my plan of action decided upon. Perhaps it may sound like too sweeping a remark to say that in adult life, when the patient is in otherwise tolerably good health, a pustular eruption is very nearly always due to syphilis; nevertheless a quite extended experience with venereal and skin patients leads me to state it as broadly as I here do, and I will relate a case which first attracted my attention to this point, and which made a lasting impression on my mind:—

Several years ago, shortly after the commencement of my professional connection with the late Dr. Bumstead, a young man of fine physique, an athlete, twenty-eight years of age, came to consult us about a large pustule seated upon his back, which was of one week's duration. On asking him about any recent venereal affection, he denied having had intercourse with women for a year past, as he had been in training for boat and foot races during that period. As to it being an ordinary ecthyma, his healthy appearance negated that idea, and yet one single pustule did not seem sufficient to base a diagnosis of syphilis upon. While we were debating what to call it he said he had something else to show; not that he considered it of any importance, but he was curious to know what it meant. He then unbuckled his trousers and showed us a magnificent syphilitic orchitis of one of his testicles. This, he said, had lasted about two or three weeks, did not pain him at all, and its size was the only cause of calling his attention to its condition. He was placed upon the mixed treatment, and in course of time the pustule and the orchitis disappeared.

Oddly enough in the course of this year, 1880, I have seen another case of gummous infiltration of the glands of the groins, which, however, had a previous history of

syphilis. I have ventured to report the case here presented, because it lacked a history, and because I wish to emphasize certain symptoms which occurred in its course and which I believe will be of use in forming a diagnosis in similar obscure and puzzling cases.

16 WEST THIRTY-SECOND STREET, NEW YORK.

GANGRENE OF BOTH FEET; PIROGOFF'S OPERATION.

BY DR. R. MENGEL, SAN ANTONIO, TEXAS.

In November, 1880, a Mexican pauper, aged fifty-one years, was admitted to the charity hospital with spontaneous gangrene of both feet. The gangrene reached from the toes to Chopart's joint with a sharp line of demarcation. The third day, with antiseptics and Esmarch's bandage, I performed Pirogoff's osteoplastic operation on both feet, Drs. B. E. Hadra and Adolf Hertf assisting. The vessels were tied with fine carbolized silk, and but little bleeding and no after hæmorrhage occurred. As the right calcaneus was sawed through, a small place infiltrated with pus presented itself, which was removed. After careful dissection and disinfection of the stumps they were provided with drainage tubes and bandaged with absorbent cotton, reaching up to the knee-joint. On removal of the bandages the second day the wounds looked fresh and seemed united by first intention; they were again disinfected with a weak solution of carbolic acid through the drainage tubes and then bandaged with plaster of Paris; which had to be removed the next day, being soaked with serum. The temperature was always normal.

Strange to say, until the second week the wounds made a most satisfactory progress, discharging little but laudable pus. At this time I was greatly alarmed from the fact that the patient twice soiled his bed, having taken a purge, and as he failed to report his condition he was left for two days in his helpless and unclean state; whereupon an enormous decubitus of the sacrum developed itself. The whole anterior ligaments of the os sacrum and tubera ischii were laid bare and the gluteal muscles and soft parts around the anus sloughed. With good care afterwards and stimulating diet and medication his general condition improved. The decubitus was disinfected with salicylic powder and solutions of permanganate of potassa. Later it was dressed with zinc ointment. From the beginning of the decubitus also the stumps began to appear worse; the discharged pus was very foul; the drainage tubes had to be removed, and the wounds were disinfected with a strong solution of carbolic acid. A phlegmonous inflammation of the left leg and erysipelas set in, which reached to the thigh. A deep incision was made above the condyle along the tibia, when a pint of pus and necrotic tissue was evacuated. After this, the inflammatory symptoms of the leg disappeared, but the other (right) leg showed a very severe erysipelas, especially of the upper portion, reaching upward over the whole body. During this period the patient was well nourished with egg nog, quinine, and whiskey, and different preparations of iron were given, the muriated tincture of iron proving the most beneficial. Under this regimen the general condition again improved, so that the stump wounds which were disinfected every second day with carbolic water, granulated freely.

Up to date, after six weeks, the patient has remarkably improved. The bed-sores are granulating well, the stumps are also uniting, especially the right one.

The above case is surely an interesting one and worthy of publication, inasmuch as it shows what antiseptic treatment with good care can accomplish even in a debilitated old man. Of two other Mexicans, one of whom I exarticulated the hand for total spontaneous gangrene, and on the other the toes, the first died after nine days from tetanus, being in the highest degree emaciated and neglected before the operation, the other died at the end of the fourth week from general marasmus. All of these cases were operated at the joint nearest to the line of demarcation, and in none secondary gangrene of the stumps developed. It is well known that most patients affected with gangrene die from marasmus and if, therefore, the general nutrition can be restored by proper treatment, amputation is surely the most rational means of treating a decayed member—which gradually destroys the vital powers through septic self-infection.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROICH, M. D., SECRETARY.

JANUARY 24, 1881. DR. JAMES C. WHITE, permanent chairman, presided.

DR. BOLLES reported some interesting cases of pneumonia. Vide page 104 of this journal.

DR. MIXOT thought the cases in which lobar pneumonia was followed by chronic lung disease (phthisis) were rare, though they sometimes occurred. As a rule, the lung was left uninjured by pneumonia, an evidence of the non-inflammatory character of the latter disease. In a few cases he had seen a severe catarrhal condition of the lung, which eventually recovered, resulting from pneumonia. Where there existed a strong proclivity to phthisis it was reasonable to suppose that the disease would be developed by pneumonia, but he thought this seldom happened.

DR. KNIGHT said that he had been struck with the insidious development of croupous pneumonia in several cases recently. In one, a lady of about thirty years, there had been bronchitis two weeks, then a gradual consolidation of one lower lobe and gradual resolution, the whole process being of about six weeks' duration. In another, a child of ten, walking about, a persistent hacking cough attracted attention to the chest, and commencing consolidation was found, which went through the usual signs, and the patient made a good recovery. There was no pain, but little fever, and nothing which suggested such a serious condition. Dr. Knight said that he should be inclined to think that in the last case reported by Dr. Bolles a circumscribed empyema had broken into the air-passages, rather than that there had been a true abscess of the lung. Pulmonary abscess in acute pneumonia was a very rare occurrence. It was attended usually with exceedingly grave symptoms,—rise in temperature and pulse, and perhaps delirium. The sputa was bloody or chocolate colored. Microscopic examination might show elastic tissue of the lung.

DR. BOLLES said that no microscopic examination of the sputa was made in his case.

DR. KNIGHT remarked that the remaining contraction of the chest pointed to the previous occurrence of pleuritic effusion.

DR. BOWDITCH spoke of the importance of not sending patients with troublesome coughs to the seaside, as much harm is done by their going even so short a distance as to Swampscott, and in reply to a question he stated that although the South Shore might be less harmful than the North, yet he would not advise either, and that he would not even send these patients to the shores of Buzzard's Bay.

DR. KNIGHT mentioned the excellence of Eastman's Hotel, which is situated in Southern Georgia, the best dry region of the South.

DR. A. T. CABOT showed a jagged fragment of mutton bone measuring three by three and a half cm., which he had removed with the bristle probang from the œsophagus.

The patient, a middle-aged man, had swallowed it a week before he was seen, and for the greater part of that time it had lain just above the cardiac orifice, from which position it was dislodged and removed.

DR. BOWDITCH asked permission to refer to the following case, in order that he might ask a question in reference to the treatment of similar abdominal diseases. A healthy girl came from skating; she thought herself well and appeared so. At tea time she felt that her stomach was somewhat out of order, and she ate but little food, because she thought it best not to take the usual amount. The next day she vomited food that had been taken three or four days before. But she still had no serious symptom. The abdomen, until death, which took place in a few days, was never distended. The sole thing noticed was a little tenderness about the caecal region, but no tumor was felt there. Two days before death she suddenly vomited about half a pint of grumous blood. The next day the same symptom occurred, and she became worse. She died in a few days only from the time of the first attack, having never shown any marks of positive local disease, save the slight pain in the caecal region, above mentioned. The diagnosis was not made before death. At the autopsy there were found splæchus of a part of the appendix cæci and a small quantity of pus about it. No general peritonitis. The question Dr. Bowditch would ask was this: Shall we not in cases like this, where the patient has evidently some local acute or chronic trouble in the abdomen threatening death, make an incision through the abdominal walls and seek for the difficulty? Under the spray as used of late by ovariologists such an operation is comparatively innocuous. Dr. Bowditch believed that such an operation will be considered wholly proper in a few years, if it be not now. Among the profession thoracotomy, when it was first performed by Dr. Wyman, was as much opposed as an abdominal section, for such a case as had been alluded to, would be now. But, as in the case of aspiration of the chest, Dr. Bowditch was confident of the ultimate reception of the operation by all, so he had the fullest persuasion that abdominal explorations under carbolic-acid spray will be the rule in very many cases, certainly in all where death is evidently threatened. Dr. Bowditch would like to hear the opinion of members upon the question. Dr. Bowditch said that in these suggestions he did not mean to include cases of evidently malignant disease.

DR. E. G. CUTLER showed specimens from three

cases of phthisis occurring at the Carney Hospital. In the first there was little left of the right lung, an enormous cavity taking up all but a small portion of the lower lobe behind. There was a round ulcer of the stomach situated on the lesser curvature near the pylorus, and about as large as a quarter of a dollar. Tuberculous ulcers were also found in the intestine. The case was of long standing, and nothing in the symptoms pointed towards the ulcers. In the second case, in addition to the lung appearances, relatively old infarctions were found in the spleen and kidneys. The source of the emboli was afterwards found to be from a thrombus situated on the wall of the aorta. The patient died within a very short time after entrance to the hospital, and no history was obtained. In the third case there was amyloid degeneration of the spleen, liver, and kidneys, and the patient died of diarrhoea.

DR. ELLIS spoke of the possibility of ulcer of the stomach existing and even going on to perforation without presenting any marked clinical symptoms.

Recent Literature.

Ringworm: Its Diagnosis and Treatment. By ALDER SMITH, M. B. Lond., F. R. C. S., etc. Philadelphia: Presley Blakiston, 1012 Walnut St. 1881.

Dr. Smith, as resident medical officer of Christ's Hospital, London, has had exceptionally good opportunities to study cases of tinea, and has embodied the results of his investigations, during the last ten years, in reference to the diagnosis and treatment of cases of tinea trichophytina, in an excellent little monograph of eighty-one pages, with five illustrations, containing useful and practical hints upon these subjects, especially as to the artificial production of "*kerion*," the inflammatory form of the affection, and nature's method of effecting a cure. Many of his observations have been recently published by him in the columns of *The Lancet*, and have been noticed in the reports of the JOURNAL upon Recent Progress in Dermatology. The favorable opinions therein expressed need not be repeated, nor need they be modified as to the additional matter contained in the nine chapters of this little work, which is calculated to be of service to every medical practitioner in his endeavors to recognize and eradicate this insidious and very troublesome complaint. We call especial attention to the chapter upon Ringworm in Schools, including, as it does, the consideration of the important questions of "certificates" and "isolation."

A Pictorial Manikin, or Movable Atlas of the Human Body, showing the position of the Internal Organs by means of superposed Colored Plates. By PROFESSOR G. J. WITKOWSKI, M. D., member of the Faculté de Médecine de Paris. English Translation of Text, by ROBERT HUNTER SEMPLE, M. D., F. R. C. P., London. With Introductory Essay and Explanatory Anatomical Index, by PROF. D. A. LOOMIS, M. D., late Assistant Surgeon, U. S. A., and formerly Professor of Anatomy in the Pennsylvania Medical College. New York: Published by Joseph Cristadere. 1880.

It may be that the title-page is enough; but still we will inflict on our readers one paragraph of the Introductory. "During the history of man there has been

a universal want, a demand for something that would simplify the study of the science of anatomy; something that would attract and at the same time instruct; something that would call forth admiration and convey to the mind the wonderful mechanism, the economy, the perfect action of the various systems;—in other words, a something that should present to the eye an approximate equivalent for the dissected subject, and thus have in hand, shorn of every objectionable feature, all that was necessary to intelligently obtain accurate instruction. This want is at last supplied."

As "pictorial manikins" are certainly not new, perhaps we are to find the supply of this long-felt want in the essay. We might make several rather amusing extracts; but will content ourselves with one which may be new to sanitarians. "At each expiration the lung does not get rid of all the air it contains; the latter is renewed only gradually. Hence comes the establishment of *quarantines*, applied to vessels returning from countries where contagious maladies are prevailing." It is, perhaps, fair to say that this work does not seem to be meant chiefly for professional men; but this does not make us more favorable to it.

How to Use the Forceps. By HENRY G. LANDIS. New York: E. B. Treat. Pp. 168.

In this little book the author gives a very detailed account of the proper way in which forceps should be used, and discusses at some length the value of the instrument and the indications for its use, as well as the dangers to be avoided by beginners. About half the volume is occupied by an account of the female pelvis and of the mechanism of the delivery. The book is evidently intended for students, and as such is well fitted to teach the value of an instrument which is every year being more and more used by obstetricians. The advice given as to the use of forceps for the purpose of flexing the head seems to us dangerous unless the instrument be in the hands of an experienced and skillful operator.

— We extract a few stanzas from a poem on The Primæ Viæ in the *Canada Lancet*:—

Here the villi dip their noses;
Gifted with a wondrous power,
Not of smell, but of selection,
Of acceptance or rejection
Of the products of the hour.

Noble villi! Who instructs ye
Thus to choose our boon or bane?
How do ye secure your treasure,
How transmit it at your leisure?
Questions, yet to ask, in vain.

See that particle of butter,
Now an oil globe on its way;
The saliva lightly kiss'd it,
But the gastric juice has miss'd it,
And the purling stream has whisk'd it
In a duodenal bay.

There coquetting with a portion
Of the undigested rice,
The hepatic fluid meets them,
Pancreatic juices greet them,
And they're married in a trice.

Happy he whose daily promptings
Urge to defecation due:
Needing neither pills nor potions,
Regular, as his devotions,
Setting out on life anew.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 3, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to

HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

COLOR-BLINDNESS AMONG CONNECTICUT RAILROAD EMPLOYEES.

UNDER the head of Color-Blindness an Issue in Politics, editorial comment was made in the JOURNAL for August 19th last, on the attempts of party managers to make a dead letter of a law, then recently passed by the Connecticut legislature, for the examination of railroad employees. Through an esteemed correspondent, Dr. Chamberlain, Secretary of the Connecticut State Board of Health, we are enabled to give our readers the following interesting details of the subsequent working of that law.

The legislature of Connecticut, last year, passed a law requiring all railroad employees engaged in moving trains to be examined for color-blindness and visual power. The law interpreted in its letter and spirit was rather rigorous, decidedly in advance of general knowledge upon the subject, and somewhat in advance of public sentiment. Indeed, upon the attempt to execute the law, it was found that public opinion was almost universally opposed to it, as inflicting individual hardship and injustice that were, to say the least, uncalled for. The public press generally condemned it most vigorously, and it was even made an issue in partisan politics, each party vying with the other in the endeavor to gain the sympathy of the workmen by their promises of repeal. The law, as before stated, was severe, requiring each employee to possess a certificate of normal visual power and freedom from color-blindness. The execution of the law was placed in the hands of the State Board of Health, which nominated experts and had the power to make rules and regulations under the act. The general method adopted was the now pretty well-known Hohlmgren's worsted test, with other corroborative ones, and those by reflected and transmitted light for quantitative tests. Engineers and firemen were placed in one class, and the tests very much reduced in severity for all others; reservation was also made by a special rule in favor of all old employees, so that any apparent injustice could easily have been looked into and corrected. It so happened, however, that at the outset of the examinations several engineers, closely connected with the principal officers of one of the most influential roads, were found more or less defective, and others, of greater or less influence politically, were involved. A special appeal, signed by six thousand or more, including nearly, if not all, railroad presidents and prominent officials, as well as by leading politicians, was presented to the Board of Health,

asking that the methods of examination be entirely changed, and practical tests only employed, such as the flags and lanterns used in signaling. The great cry was that the men be tested by the tools with which they worked, by practical tests, — as if those were not practical which ascertained the facts surely and with the greatest ease and rapidity. In deference to these representations, however, those condemned by the worsted system were allowed a further trial by flags and lanterns, at eighty rods. The results of this were somewhat surprising to the men. Out of twenty-four men examined by Dr. Bacon, and found color-blind by the worsteds, twenty-one failed by flags and lanterns, and the others answered more or less unsatisfactorily. Similar results were obtained by Professor Carmalt, the other examiner.

One very important fact was elicited by Professor Carmalt, as follows: "Among those in the first class (engineers and firemen) found deficient in color perception, but *one* was over thirty-two years of age, the average age of those thus affected being just thirty-one years. With this exception the defect was only found in this class among men considerably below the average age of their class, which is thirty-six and one half years. The youth of the men with this defect goes to show that, though the tests applied on the roads are too crude, too uncertain, ever to detect the defect as such, these men are actually eliminated from the service before they reach the average age of their class by a further experimentation with the lives of the passengers and the property of the corporations." At how much sacrifice of life and property we are unable to say.

There were 1,950 employees examined, divided as follows: —

		Defective Vision.	Defective Color Sense.
Engineers,	291	33	9
Firemen,	285	18	8
Total first class,	576	51	17
Conductors,	202	17	7
Brakemen,	635	68	32
Station agents,	212	35	6
Flagmen, etc.,	325	25	6
Total second class,	1,374	145	51
Total,	1,950	196	68

The defects in these varied very much in degree. The average ages of engineers has already been given. The average age of firemen with defective color perception, examined by Professor Carmalt, was twenty-seven years; of conductors, forty-seven; brakemen, twenty-seven; switchmen, forty; station agents, forty. Average age of all classes, thirty years and six months. Some very singular facts were discovered by these examinations: for example, a brakeman serving on a night freight train was found to be so near sighted that he could see only a few inches from his face, and yet he had met with no accident for eleven years. Men in responsible positions, serving on fast trains, were found with very defective vision and progressive disease, as double cataract. Congenital defects in one eye, or the results of injury in one eye, which

long training had compensated for, reduced the number to be rejected, to some extent, the defect being non-progressive in its character. Many occupations were changed: in regard to brakemen, for instance, it was learned that the place in the middle of the train is much less responsible, as they there act only upon signals from the whistle, never relying on sight; so this position was given in many instances where the defects were considered too great for any other place. This reduced the number to be finally rejected very materially. There were also many whose experience and training amply compensated for the degree of defect found. In other cases limited certificates were given to those who, in course of time, would become entirely unfitted for their responsibilities, but reexaminations will readily weed out these.

The experience with flags and lanterns proved entirely untrustworthy and unsatisfactory. It gives the color-blind fully an even chance to guess right, and renders collusion with some interested friend more difficult to prevent. Both of the experts condemn these tests as of no value whatever, and thus appears to be the universal testimony of all who have used them in any way. No tests would be satisfactory to those rejected by them. There was as much fault found with the so-called practical tests by those who failed under them as with Holmgren's test by those who failed to pass it. The results of the examination showed the necessity of some such law as that passed by the legislature, and that the public are not sufficiently protected by the methods employed by the railroad officials themselves.

BOGUS DEGREES IN THE UNITED KINGDOM.

A CORRESPONDENT of the *Lancet* puts the following questions in a communication to that journal:—

(1.) Is it true, as has been alleged, that the fellowship of the Royal College of Surgeons of Edinburgh can be obtained *without examination*, upon the payment of the necessary fee?

(2.) Is it a fact that the F. R. C. S. of Edinburgh is a sufficient qualification for the office of surgeon to any (or some) of the metropolitan hospitals?

(3.) Can a candidate who has failed to obtain the double Edinburgh qualification (L. R. C. S., L. R. C. P.) obtain the L. R. C. P., or some similar license, and then be straight away elected to the F. R. C. S.?

In reply, the editor says there is no doubt or mystery about the fact that the Edinburgh College does virtually sell its fellowship; that is to say, if any person already possessed of a license in surgery from any licensing body in the United Kingdom applies to the Edinburgh College for a fellowship, and can accompany his petition with testimonials showing that he has not broken any of the lesser commandments, the constitution and custom of the college are such that he will receive its fellowship on payment of a certain sum. Moreover, the fellowship of the Royal College of Physicians of Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are to be had on the same easy and pecunious terms, without examina-

tion and *in absentia*, as in the case of the Edinburgh College.

To illustrate the working of what the *Lancet* calls this "monstrous system," it quotes the following from the report of the sub-committee on medical education appointed by the committee of council of the British Medical Association:—

"We may mention the case of a student who presented himself at the Royal College of Surgeons, London, and was rejected. He immediately started for Edinburgh, where he was again rejected. Upon this he went to Glasgow, and passed. He registered as a qualified practitioner, forwarded certain sums of money to Edinburgh, and, as qualified practitioner, was made a Fellow, without further tests, by the very college which had, not long before, rejected him as unfit, by examination, for the license!"

In regard to this state of things in Scotland, the editor expresses his feelings thus:—

"In the medical world a fellowship of a college of surgeons implies merit. It implies in the English college an extended education and the passing of a very severe examination. It implies probably a pecuniary outlay of nearly four hundred pounds over and above the cost of an ordinary medical education. The possession of a fellowship is a condition of obtaining office in metropolitan hospitals, if not in provincial ones. Can there be anything out of the region of sacred things more serious than to preserve the point of such a distinction? But here is a royal college of great respectability and renown actually selling it! So that two men may be competing for an appointment of great responsibility, for fitness for which a fellowship of a college of surgeons is thought the best security, and yet in the one case the fellowship is a real thing, in the other it is entirely unreal; in the one case it has been worked for and won, and in the other it has been—bought! Can there be a greater unfairness than for a royal college to send a man into a community, to work among other men, with such a piece of tinsel to his name?"

One of the British medical corporations was reported, some years since, according to the same authority, to have made ten thousand pounds in one year by the virtual sale of its lowest qualification.

We do not refer to these transactions as putting the traffic of our own diploma mills in any better light, but it must be confessed it is soothing to observe that the human nature is not all on this side of the Atlantic, and that there is even some of it in soulless corporations, and British ones at that.

MEDICAL NOTES.

—Dr. C. F. Folsom has reconsidered his acceptance of the position of superintendent at the Danvers Insane Asylum. He has been nominated, and will doubtless be confirmed, to the vacancy on the National Board of Health, caused by the resignation of Dr. H. I. Bowditch.

—We are pleased to learn that there is a good prospect that the present Congress will make an ap-

propriation for the publication of two more volumes of the Index Catalogue of the Library of the Surgeon-General's office.

— We call our readers' attention to the obituaries of two eminent country practitioners of Massachusetts, lately deceased. They were the oldest members of the Massachusetts Medical Society at the time of their death, and had labored honorably in professional harness for more than sixty years. Both Dr. Spofford and Dr. Alden were admirable models in many ways of what the physician outside of large cities was expected to be, and it would be a misfortune for the State should this class of practitioners become extinct. They were not only skillful, kind, and laborious as physicians, but helpful and interested in all things pertaining to the welfare of their fellow-men.

— The Alumni Association of Jefferson College proposes to entertain Dr. Hamilton Osgood, who delivers the annual oration before it, by a supper at Augustin's.

— Mr. Bergh has before the New York legislature the following bill:—

An Act to prohibit the Vivisection of Animals. The people of the State of New York represented in senate and assembly do enact as follows:—

SEC. 1. Every person who shall perform, or cause to be performed, or assist in performing, in or upon any living animal an act of vivisection shall be guilty of a misdemeanor.

SEC. 2. The term "vivisection" used in this act shall include every investigation, experiment, or demonstration producing, or of a nature to produce, pain or disease in any living animal, including the cutting, wounding, or poisoning thereof, except when the same is for the purpose of curing or alleviating some physical suffering or disease in such living animal, or in order to deprive it of life when incurable.

SEC. 3. This act is to take effect immediately.

— The annual meeting of the Salem (Mass.) Hospital was held lately. The report states that 165 patients were admitted during the year, and 21 deaths occurred. There were out-patients—medical, 187; surgical, 65; dental, 245; eye and ear, 349. Total number of visits to hospital by patients, 3438. The contributions "to the nameless" were \$1270.93; bequest of the late Mrs. Weston, \$1000. The total receipts were \$10,716.64. The expenses were \$9712.98.

— We feel sure the writer of the following note will bear us no malice for extending the fame of his invention:—

SIR.—I would like to draw attention to a suit for dressing at one movement. I got one two months ago, and I find that, when my night-bell rings, I can be dressed—with entire suit, white collar and cuffs complete—and by the side of my client in the street under one minute and a half. The suit is registered and made by James Maltby, 8 Hanover Place, Regent's Park, N. W., and costs three guineas. There is no waistcoat; but the coat and trousers are attached by elastic, so that the trousers are put on, then the coat, and all is complete. Of course, socks, boots, and hat are to be put on; and it is these which take up the

most time. This "united suit," as it is called, robs the sound of one's night-bell of half of its horrors. I am yours truly,

LONDON, December 7, 1880.

ANGLO-SCOTT.

— Jonathan Hutchinson writes the *British Medical Journal* in strong advocacy of ether in preference to chloroform. "I should consider myself," he says, "very culpable if I ever permitted the use of chloroform except in certain cases. The exceptions are the old and the very young: under six months and over sixty years, chloroform, I think, is preferable. . . . I can testify in the strongest possible terms to my own feeling of security with ether and of risk with chloroform." Hutchinson's reasons for using the latter in the aged and infants are, "With aged persons ether often disagrees, leaving headache and tendency to stupor for many hours afterward. Chloroform, on the contrary, agrees with the old, and appears in them almost free from risk. The same freedom from danger seems to exist in early infancy."

NEW YORK.

— At the last meeting of the Board of Health the following ordinance was passed:—

"There shall not be a public or church funeral of any person who has died of small-pox, diphtheria, scarlet fever, yellow fever, typhus fever, or Asiatic cholera, but the funeral of such persons shall be private; and it shall not be lawful to invite or permit at the funeral of any person who has died of any of the above diseases, or of any contagious or pestilential disease, or at any of the services connected therewith, any person whose attendance is not necessary, or to whom there is danger of contagion thereby." Violation of the ordinance will be a misdemeanor, punishable by a fine of \$250.

— There are now about 175 cases of scarlet fever reported each week. By the latest reports, diphtheria and small-pox were shown to be appreciably diminishing.

— In the court of special sessions Julius Meyer, a butcher, has been found guilty of a violation of the sanitary code in selling diseased meat, and sentenced to three months' imprisonment in the penitentiary and the payment of a fine of \$250. At the trial it was found that the man had been engaged in the disreputable business very extensively, and for a considerable time. Acting under the instructions of Sanitary Superintendent Day, one of the officers of the sanitary squad of the police force had represented himself as a sausage-maker, and Meyer had agreed to supply him with one hundred pounds of decomposing meat a day, at the rate of five cents per pound.

— Mrs. O'Connor, who has been on trial in Jersey City for the murder of her three children, has been acquitted on the ground of insanity. After the verdict had been rendered, Judge Knap, before whom the case was tried, appointed Drs. Varick, Converse, and Culver, of Jersey City, a commission to inquire into the present mental condition of the woman; and they reported that the woman's insanity is inherited, and that the paroxysm in which she killed her children

was developed in consequence of want of proper nourishment and her debilitated physical condition. At present, she appears to be perfectly sane; but they believe that if her system should be allowed to run down again, the paroxysm would be liable to return, and she might, if the opportunity offered, kill the rest of her family. Under the circumstances, she has been sent to the insane asylum at Morristown until, in the judgment of the physician in charge, it may be deemed safe to allow her to go at large.

— At one of his clinics at the College of Physicians and Surgeons, Dr. Fox, lecturer on dermatology, recently introduced an interesting case of leucodermis in the person of the "African leopard boy," now on exhibition at a museum on Broadway. The boy was eleven years old, he said, and of pure negro parentage. At birth he was entirely black; but when he was about three years of age white patches began to appear on his body, and these have increased in size and number until now a considerable part of his arms, chest, abdomen, and legs is white in irregular blotches, while around these the skin is of a *café-au-lait* color. There is also a white spot on his forehead, which extends backward for several inches upon the head; the hair likewise being white over it. The face (with the exception of the patch upon the forehead), neck, hands, feet, and back are entirely black. Except as to color, the skin is everywhere normal in character. Dr. Fox has had the lad under observation for some time now, and says that the white area is increasing every year. He predicts that some day that he will become an entirely white negro.

— At the last meeting of the Board of Health the following table was presented by the registrar of vital statistics: "The following deaths from zymotic diseases, which were influenced or aggravated by defective plumbing, allowing sewer-gas to enter the apartments of the victims, occurred in the year 1880:—

Diseases.	Total Deaths Reported.	In Houses containing less than four Families.	In Houses containing more than four Families.	Institutions.
Measles.....	484	100	320	64
Scarlatina.....	610	165	418	25
Diphtheria.....	1,381	399	950	31
Membranous Croup..	903	226	664	14
Whooping Cough....	276	48	190	28
Typhus Feve.....	3		2	1
Typhoid Feve.....	237	52	165	75
Total.....	3,894	990	2,655	239

Diarrhœal diseases, all ages, 3960; diarrhœal diseases, under five years, 3489.

At the same meeting Sanitary Inspector Morris reported the result of the inspection of twenty-one houses in which diphtheria had occurred within two weeks. In twenty out of the twenty-one houses, there were bad plumbing and defective house-drainage. Nearly all the cases were in tenement-houses, and offensive odors had been complained of by the tenant.

In this connection an instructive case has just come to light in Brooklyn. Some time ago a gentle-

man bought a fine residence on Columbia Heights. He was careful in his selection on the score of health, and in order to avoid every possible danger, he had the old plumbing work entirely removed, and put in the most approved system in place of it under a competent plumber connected with the Brooklyn Board of Health. Every precaution that science and experience could suggest was taken against the prevailing danger of sewer gas and other noxious influences. One point only was overlooked. When the gentleman purchased the house his plumber recommended that it should be thoroughly fumigated in order to destroy any possible germs of disease which might be lurking in it; but as the agent who sold the house assured him that there had not been a case of sickness in the house for many years, he concluded that this would be unnecessary, and it was not done. Last week the gentleman's only son, aged four years, died of diphtheritic croup which ensued upon an attack of scarlet fever; and now it is discovered by an examination of the records of the Brooklyn health office that there has been a series of diphtheria and scarlet fever in the house, running back for several years. Such an experience suggests that the sanitary history of a house is as important as its situation and surroundings.

— The Alumni of the Medical Department of the University of the City of New York gathered for the twelfth annual dinner the evening of January 26th at Delmonico's. Speeches were made by Dr. D. B. St. John Roosa, the retiring president, the Rev. Dr. Crosby, William Allen Butler, and others. William Winter read a poem. Previous to the dinner, officers were elected for the ensuing year.

— Dr. Hammond's daughter, the Marquise de Lanza, has just completed a novel, to be published by the Putnams, the plot of which turns upon the idea of double consciousness. The heroine, while in the "second state," engages herself to be married, and when she recovers her normal condition has forgotten all about it. Dr. Hammond will write a preface to the book on the subject of double consciousness.

— Hospital Saturday and Sunday in New York yielded, clear of all expenses, forty-one thousand dollars.

CHICAGO.

— The Illinois training school for nurses, to be established in Cook County Hospital, Chicago, seems now in a fair way to be inaugurated at an early day. A meeting of citizens was recently held in its interest, at which subscriptions to start it were solicited and several thousand dollars were subscribed. Two wards of the hospital have been put at the service of the school. Should the scheme be a success it is not unlikely the whole institution will be placed under the system. The school is to be conducted on a plan similar to the school in connection with Bellevue Hospital in New York city.

ST. LOUIS.

— At the annual meeting of the St. Louis Medical Society, held January 8, 1881, the following officers

were elected: president, Dr. H. H. Mudd; vice-president, Dr. R. S. Anderson; treasurer, Dr. Wash E. Fischel; recording secretary, Dr. A. H. Ohmann Dumesnil; corresponding secretary, Dr. M. H. Post. The following Saturday evening, January 15th, Dr. Mudd, as an inaugural address, made some remarks upon cerebral localization, which will be reported in full in the JOURNAL. It was illustrated by charts and by several brains hardened in nitric acid by the process of Giacomini.

— There are from one to three clinics a day, excepting Sundays, at the St. Louis City Hospital.

— By a city ordinance it is so arranged that any medical school in the city may conduct clinics at the City Hospital, provided every member of the faculty of said school is a registered physician of the city, the school selecting their own clinical instructors. At present Dr. John T. Hodgen, of the St. Louis Medical College, holds two surgical clinics at this institution each week. Dr. E. F. Smith, of the same school, holds two medical clinics each week, and Dr. John Green conducts one or two eye clinics a week for the benefit of the students of this school. Dr. A. P. Lankford, of the Missouri Medical College, and Dr. P. G. Robinson, of the same school, hold, respectively, two surgical and two medical clinics a week. Dr. Louis Bauer, of the St. Louis College of Physicians and Surgeons, holds one surgical clinic a week, and Dr. Hazard, of the same school, a medical clinic. The homœopathic and eclectic schools each have a clinic a week.

— There have recently been organized in the city two new medical schools.—one “regular” and one “eclectic.” They have demanded the privilege to hold clinics at the City Hospital, and this has so increased the number of clinics, already too large, that the health commissioner has been instructed to appoint a certain number of clinical lecturers. These are to deliver lectures on fixed days to which the matriculants of any or all of the schools in the city will be admitted as they see fit to attend.

Miscellany.

THE LATE DR. SPOFFORD.

MR. EDITOR.—The semi-annual meeting of the Essex North District Medical Society was held at the Essex House, in Lawrence, on Wednesday, January 19th, at one o'clock P. M.

The following memorial was presented on the death of Dr. Jeremiah Spofford, of Groveland, the senior member of our society, and it was voted that a copy be sent to the JOURNAL for publication. Yours respectfully,

GEORGE W. SNOW, M. D.,

Secretary Essex North District Medical Society.

NEWBURYPORT, January 27, 1880.

The committee appointed by this society to prepare some suitable testimonial to our deceased Fellow, Dr. Spofford, respectfully present the following

MEMORIAL.

Dr. Jeremiah Spofford was born in New Rowley, now Georgetown, Mass., December 8, 1787. His ancestors were of that sturdy Puritan stock that gave character and vitality to the

early history of New England, his father and grandfather having both engaged in the great struggle which resulted in our national independence. Dr. Spofford's early education was limited to the scanty tuition of the district school, with private instruction in Latin and kindred studies under the direction of Rev. Isaac Bramon, the minister of the town. He made the most of his spare hours, and commenced the study of medicine in 1810, with Drs. Whiton and Parkhurst, of Winchendon, eking out his scanty income by teaching the district school in his native town.

In June, 1813, he was licensed as a practitioner of medicine by the censors of the Massachusetts Medical Society at Worcester. After practicing for a short time in Hampstead, N. H., he removed to East Bradford, now Groveland, Mass., in 1817, where he was the sole practitioner for more than forty-seven years, continuing in active service for nearly sixty years. His whole professional career extended over the exceptional period of sixty-seven years.

His domestic relations were of the most delightful character. In 1813 he married Mary Ayer Spofford, of Jaffrey, N. H., with whom he lived for over sixty years. Of the nine children of this typical New England family, seven survive to bless the memory of their honored parents.

As a member of this society, Dr. Spofford showed his lifelong interest and devotion by his regular attendance upon all its meetings, and by his valuable contributions to its scientific, literary, and social life. To him are we largely indebted for the preservation of the historical incidents of the society, and his biographical sketches of its early membership are among our most valuable archives.

His vigorous brain, his indomitable will, his tireless energy, and stern integrity furnished the elements of his success. His mind was controversial, and hence he probed every subject with which he came in contact with the sharpness of his analysis and the force of his terse logic. He was not an easy antagonist in the discussion of professional and social ethics or political economy. He was cautious as to new methods, and only accepted or adopted them after the most careful scrutiny.

These sturdy traits had a controlling influence upon his professional career. As a physician, Dr. Spofford was cheerful, faithful, and persistent in the care of his patients, gentle and benevolent to the unfortunate and the poor, and true and loyal to the standard ethics that govern professional intercourse. As a citizen, he was foremost in the promotion of the highest interests of the community in which he dwelt. This was manifest in his exertions for the educational and material prosperity of his fellow townsmen, while in the broader range of business and official life his influence was widely known and felt. And now this life, so crowded with activity, is brought to its close, and he has gone to his rest, soothed and comforted by the tender ministrations of his children, and strengthened by the hope of a blessed immortality.

RESOLUTIONS.

In more formal recognition of our respect for our venerable deceased Fellow we offer the following resolutions:—

First. That in the death of Dr. Jeremiah Spofford, the senior member of the Essex North District Medical Society, we recognize the loss of one who for more than half a century has stood firm as a pillar between the true and the false, the right and the wrong, in education, religion, and medicine.

Second. That we record with pleasure our appreciation of his valuable services to this society by his contributions to its literature, by the wisdom of his counsels, and the influence of his example.

Third. That we extend to the family of the deceased our sincere sympathy in their bereavement.

Fourth. That this memorial, with the resolutions, be entered upon the records of this society, and that a copy be sent to the family of our deceased Fellow.

JOHN CROWELL, }
G. W. COWSWELL, } Committee.
G. W. GARLAND, }

HAVERHILL, January 19, 1881.

EBENEZER ALDEN, M. D.

DR. EBENEZER ALDEN, the oldest resident of Randolph, Mass., and, we believe, at the time of his death the oldest member of the Massachusetts Medical Society, was born at Randolph, March 17, 1788, was graduated at Harvard College in 1808, pursued his profes-

sional studies with Nathan Smith, M. D., at Dartmouth College, where he received the degree of M. B. in 1811, attended the lectures of Drs. Rush, Barton, and others in Philadelphia, and received the degree of M. D. from the University of Pennsylvania in 1812. He settled as physician in his native town, where he has resided during his entire life. He was elected trustee of Phillips Academy and Andover Theological Seminary in 1837, remaining in office till compelled to resign, a few years since, by growing infirmities. He was one of the earliest trustees of Amherst College, and long remained the oldest member of the board, and was one of the original trustees of the Thayer Academy of Braintree. With the American Board of Commissioners for Foreign Missions, the American Education Society, and other kindred organizations he was officially associated. He was also a veteran member of the board of directors of the Randolph National Bank. Dr. Alden married a daughter of Captain Edmund Kimball, of Newburyport, by whom he had six children, three of whom survive him. He was descended through both father and mother directly from John Alden of the Mayflower. For many years he was an active member of the Massachusetts Historical Society, always greatly interested in all genealogical and antiquarian researches, and frequently contributed to its records sketches of prominent physicians. He bore the same name as his father, who was a distinguished physician of the last century. For the last five or six years of his life he was entirely blind.

OBITUARY.

MR. EDITOR, — "Dr. Walter W. Larrabee, of Saco, Maine, twenty-five years old, was found dead in his office Saturday morning, January 15th, with a bottle of chloroform beside him," as briefly reported in the daily press.

Dr. Larrabee had been settled in Saco since his graduation from Harvard Medical School in 1879. He had many acquaintances among the physicians of New England, who will learn with deep regret of his sudden death, knowing him as an honorable man, an earnest student, an able and conscientious practitioner. Some among them feel not only sorrow at the loss of a brother physician, but the keener pain of separation from a loved and trusted friend, warm-hearted and unselfish.

Dr. Larrabee had been for some years a sufferer from neuralgia. Refusing to use morphia through fear of becoming a slave to the drug, he had relied chiefly, of late, upon subcutaneous injections of chloroform, resorting, when the pain seemed past endurance, to the inhalation of ether. During the last three days of his life he was deprived of rest by the tortures of facial neuralgia, and at last attempted to procure a few moments' freedom from pain by the inhalation of the treacherous drug which ushered him from the sleep of anæsthesia into the sleep of death. As it has been suggested that cardiac disease may have contributed to a fatal result, it may be proper to state here that a careful physical examination, made about a year ago by an eminent specialist of Boston, detected no evidence of disease, cardiac or pulmonary, and no symptoms have since arisen to indicate its existence.

G. H. GARDNER, M. D.

GREAT FALLS, N. H., January 20, 1881.

PHILADELPHIA LETTER.

MR. EDITOR, — The annual meeting of the Academy of Surgery was held on the 7th inst., the occasion being honored by the delivery of an able and interesting address by the president, Professor Gross, on John Hunter and his pupils,¹ which was delivered in the Hall of the College of Physicians. The subject had proved so engrossing² to the author that he found in collating his material that he had far exceeded his original design, and had written a monograph before he was aware; he therefore only read selected portions on the evening named. The book will shortly be issued by Presley Blakiston, and will contain about one hundred and fifty pages (small octavo), with a portrait of Hunter as frontispiece. The venerable professor retains his vigor, and shames many of the younger men by his industry and application. He still lectures in the same clear, impressive style that his old students are so familiar with, and does not seem to have grown a day older, for the last decade, at least. At the first of the year he completed a three months' term of service in the surgical clinic, during which he performed a number of major operations, including ovariectomy, lithotomy, and the removal of tumors, involving careful dissection and much labor. The lectures and clinics of the Nestor of surgery are always well attended, as the old master is a great favorite with the students.

To turn to affairs at the University, the most welcome intelligence is that Prof. Wm. Pepper has been elected by the board of trustees as provost, and has accepted the position. Dr. Pepper has distinguished himself by his efforts to advance medical education in this country, and especially by his devotion to the interests of the university, whose claims he has ably and successfully advocated. As a result of this presentation of the subject, and the able appeals made by Professor Pepper, several large donations have been made to the university. One of the latest of these is one by Mr. Henry C. Gibson, who has offered to build a new wing to the hospital, for the especial use of incurable patients, at a cost of about fifty thousand dollars. The conditions attached to the gift are that it shall be ready for the reception of patients on October 1, 1881. It is intended that this new wing shall have the latest and most approved appliances, and the plans are, therefore, to be submitted to a committee of experts before adoption. The addition to the hospital will be about one hundred beds. To aid the endowment fund a grand charity ball will be held at the Academy of Music some time during this coming month, which will be one of the social events, and doubtless a grand success.

The two large medical schools are so prosperous that the subject is agitated of starting a third; the site has been selected by common rumor, and several of the faculty have been named by the same authentic dictum. It is said, moreover, that this new school may be developed during the coming summer. Of this more anon. I refrain from mentioning names at present.

Professor Da Costa has had an interesting case, a full account of which will soon be published, under treatment for the last month or two at the Pennsylvania Hospital, of trichiniasis in a German of about twenty-one years of age. The case was brought into the ward as one of muscular rheumatism with fever,

¹ See pages 73 and 97.

² N. B. No punishment.

headache, and some vomiting on the day of admission. The man's face was pale, and had a bloated look, the feet were also somewhat swelled, but were not decidedly oedematous. The principal symptoms were vomiting, which was not persistent, however, constipation, rather obstinate, pulse accelerated, but above all were observed great muscular soreness, tenderness, and stiffness, so that he was constantly changing his position in the bed on account of the pains, which kept him from sleeping at night. With this, then, was headache of a dull character, some vertigo, and a temperature of 103.5° F. to 101° F. A diagnosis of trichiniasis being made provisionally, it was confirmed by cutting down upon the deltoid muscle and removing a small fragment for examination, in which were seen several small trichinae. Four weeks later, when the patient appeared to be convalescent, and his temperature had been normal for three weeks, another specimen was obtained with a trocar and harpoon by which some encysted trichinae were extracted, one, after being disturbed, exhibiting very lively movements, which were kept up for more than an hour while under the microscope.

The latter specimen was obtained by a new style of muscle-harpoon, invented by Dr. Hart, of the resident surgical staff of the hospital; it accomplished the purpose very well, after trial of Duchenne's harpoon without success. As this instrument will be made the subject of a communication, it will not be described here.

An interesting case, apparently of syphiloma of the larynx with progressive dyspnoea, also occurred lately in Dr. Da Costa's wards, where impending death from asphyxia was prevented by tracheotomy, performed by Dr. S. Jiminez, resident physician. The operation was performed a week ago, and afforded immediate relief; the patient is now doing well, although he was apparently moribund at the time of operating. The ordinary tube and cannula were employed.

The number of deaths from small-pox in the city continues comparatively high, although the epidemic, which was a light one, is now losing its force. In connection with the subject of revaccination, the following case will prove instructive: a gentleman past middle age, of rather full habit, and a sufferer from chronic Bright's disease, was vaccinated last week by his physician. In three or four days he perished from erysipelas. This possible danger is frequently overlooked, but nearly every practicing physician can recall cases in which the resulting inflammation and angiolentitis was very much more than was agreeable to the patient, if not actually threatening life. The vaccine physicians appointed by the Board of Health since our last epidemic, ten years ago, have so generally vaccinated our poorer population that there is at present but little material for an epidemic, otherwise we would doubtless have had to chronicle a veritable plague instead of a mild epidemic.

The County Medical Society held its annual meeting on the 19th instant, and elected the following officers:

President, Dr. Albert H. Smith; Vice-Presidents, Drs. H. Y. Evans and Charles K. Mills; Censor, Dr. F. P. Henry; Secretaries, Recording, Dr. H. Lefmann, Assistant, Dr. Jas. D. Nash, Corresponding, Dr. John B. Roberts, Reporting, Dr. Frank Woodbury; Treasurer, Dr. William Welch; Librarian, Dr. M. O'Hara.

The society is in a prosperous condition, with over three hundred members, a growing library, and pub-

lishes a very creditable annual volume of Proceedings. Its conversational meetings are held on the second and fourth Wednesday evenings of each month at the College of Physicians, and one or two papers upon practical topics are presented at each meeting. During the winter two receptions were given to the members of the society by the president, Dr. Albert H. Smith, which were well attended and generally appreciated as a means of extending mutual acquaintance and sociability. It is hoped that this good example will find imitators. By the advice of prominent members of the society, the refreshments were confined to coffee and sandwiches, in order that the expense might not prove onerous to those who may wish to continue these highly enjoyable gatherings. They are all the more necessary in this city, because men may live within a few rods of each other and never become acquainted, except through such a medium as the above, or the annual meetings of the State Society.

At the annual meeting of the College of Physicians the old officers were reelected for the ensuing year. The librarian, Dr. Bridges, resigned on account of failing health, and a resolution of sympathy and recognition of his services to the college was entered upon the minutes. The library now contains 23,800 volumes.

A bill has been brought before the legislature protecting the physicians in the matter of privileged communications. As the law now stands the confidential statements of a patient to his medical attendant are not respected as such in our courts of law, and a physician may be made to suffer for contempt of court if he refuse answer to questions of counsel regarding such communications.

The subject of the inter-professional relations of the physician and pharmacist has been under discussion for several months in this city, owing to the constant encroachment of druggists upon the practice of the physician by unauthorized refilling of prescriptions, by counter-prescribing, but more particularly and most grievously by pushing the sale of the various patent medicines. A communication upon this question from the Philadelphia Medico-Legal Society to the County Medical Society was referred, together with the entire subject, to the standing committee on hygiene and the relations of the public to the profession. After full consideration and several conferences with leading pharmacutists, a report was presented at the last meeting of the County Medical Society, reciting the complaints mentioned, containing the following resolutions, which were adopted as expressing the sentiments of the society:—

Resolved, In order as far as possible to prevent the repetition of abuses that have arisen from the unauthorized renewals of prescriptions, that physicians be requested to write the words "not to be renewed," or words or symbols to the same effect, on prescriptions which they do not wish to be renewed, without especial orders; at the same time instructing patients in regard to the evils likely to arise from such renewals, and informing them of their wishes.

Resolved, As the diagnosis and treatment of disease belongs to the province of a distinct profession, and as a pharmaceutical education does not qualify the graduate for those responsible offices, druggists should, where it is practicable, refer applicants for medical aid to a regular physician.

Resolved, That the Philadelphia County Medical Society approves of the sentiments expressed in the

following paragraph of the Code of Ethics of the Philadelphia College of Pharmacy: "Whilst the college does not at present feel authorized to require its members to abandon the sale of secret or quack medicines, they earnestly recommend the propriety of discouraging their employment when called upon for an opinion as to their merits."

Resolutions offered by the committee on hygiene, and likewise adopted:—

Resolved, That, in the opinion of the Philadelphia County Medical Society, a druggist acts simply as the agent of a physician in compounding his prescriptions, and that it is a breach of his proper obligations to the physician to renew without his direction or furnish copies of any formula prescribed.

Resolved, That members of this society will note which druggists commit such breaches of obligations, and dissuade their patients from taking prescriptions to them to be compounded.

Resolved, That the members of this society will endeavor to have their prescriptions compounded by apothecaries who do not exhibit signs or circulars, or otherwise encourage the use by the public of patented or proprietary medicines.

Inasmuch as it was claimed that many physicians themselves prescribed patented and proprietary articles, it was further

Resolved, That it be recommended to the society to reaffirm the sentiments expressed (in Section III. Art. 1 of the By-laws), namely, "that any physician who shall enter into an agreement with an apothecary to receive pecuniary compensation or patronage for sending prescriptions to said apothecary, or who prescribes a remedy without knowing its composition, or who shall, hereafter, give a certificate in favor of a patent remedy or instrument, shall be disqualified from becoming or remaining a member of this society."

Inasmuch as many druggists claimed to be unaware of the existence of a code of ethics of the College of Pharmacy, it was

Resolved, That the trustees of the College of Pharmacy be requested to furnish each of their graduates a copy of the code of ethics of the Philadelphia College of Pharmacy.

Resolved, That the report of the committee be printed in full in the Transactions of the Philadelphia County Medical Society, with the action of the society, and that publication be asked for also in the *Journal of Pharmacy* and the *Druggists' Circular*.

All of which were unanimously adopted, and the committee discharged.

It was further resolved "as the sense of the society, that there is nothing in ethics to forbid a physician's dispensing his own medicines." F. W.

Deaths reported 2569 (no report from Chicago); 924 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 545, consumption 411, lung diseases 382, diphtheria and croup 237, scarlet fever 110, small-pox 56, typhoid fever 34, diarrheal diseases 26, erysipelas 23, measles 19, whooping-cough 17, cerebro-spinal meningitis 14, malarial fevers nine. From *typhoid fever*, Philadelphia 12, New York four, Boston, Cincinnati, and New Orleans three, St. Louis two, Brooklyn, Baltimore, Pittsburgh, Buffalo, Worcester, Fall River, and Holyoke one. From *diarrheal diseases*, New York seven, Brooklyn and Baltimore three, St. Louis, Boston, Cincinnati, and Pittsburgh two, Philadelphia, New Orleans, District of Columbia, Buffalo, and New Bedford one. From *erysipelas*, New York seven, Cincinnati four, Philadelphia, St. Louis, and Baltimore two, Brooklyn, Buffalo, Boston, Providence, Worcester, and Fall River one. From *measles*, Boston 11, New York three, Brooklyn, District of Columbia, Milwaukee, Nashville, and Malden one. From *whooping-cough*, New York six, Brooklyn five, Boston and District of Columbia two, Philadelphia and Cambridge one. From *cerebro-spinal meningitis*, New York and Philadelphia three, Baltimore two, Milwaukee, New Haven, Lawrence, Chelsea, Haverhill, and Fitchburg one. From *malarial fevers*, New York and St. Louis three, Cincinnati two, Buffalo one.

Of small-pox — cases were reported in Brooklyn; diphtheria 39, scarlet fever 13, in Boston; scarlet fever 37, diphtheria 21, in Milwaukee; diphtheria one, in Somerville.

In 37 cities and towns of Massachusetts, with a population of 1,060,966 (population of the State 1,783,086), the total death-rate

for the week was 20.25, against 21.62 and 21.31 for the previous two weeks.

For the week ending January 1st, in — German cities and towns, with an estimated population of 7,533,655, the death-rate was 23.6. Deaths reported 3423; 1609 under five: pulmonary consumption 504, acute diseases of the respiratory organs 273, diphtheria and croup 158, scarlet fever 73, measles and röteln 73, whooping-cough 64, typhoid fever 49, puerperal fever 22, small-pox (Königsberg, Berlin, Krefeld, Wesel) four. The death-rates ranged from 12.2 in Erfurt to 37.9 in Kiel; Königsberg 26.5; Breslau 25.6; Munich 27.3; Dresden 22.9; Berlin 21.6; Leipzig 19.4; Hamburg 27.8; Hanover 14.8; Bremen 20; Cologne 24.7; Frankfurt 17.6; Strassburg 25.7.

For the week ending January 8th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 21.3. Deaths reported 3109: acute diseases of the respiratory organs 363, scarlet fever 105, measles 87, whooping-cough 86, fever 39, small-pox (London 33, Birmingham two) 35, diarrhoea 32, diphtheria 17. The death-rates ranged from 13.7 in Portsmouth to 25.4 in Sunderland; Birmingham 18.1; Sheffield 18.5; London 21.3; Liverpool, Manchester, Bristol 24.3; Leeds 24.8. In Edinburgh 25; Glasgow 26.4; Dublin 31.8.

In the 20 chief towns in Switzerland, for the week ending January 8th, estimated population 523,856, there were 24 deaths from acute diseases of the respiratory organs, diphtheria and croup 16, diarrheal diseases seven, typhoid fever five, puerperal fever four, small-pox four.

The meteorological record for the week in Boston was as follows: —

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 22, 1881, TO JANUARY 28, 1881.

GREENLEAF, C. R., major and surgeon. His leave of absence, granted him in S. O. 158, series 1880, from A. G. O., extended to May 1, 1881. S. O. 20, A. G. O., January 26, 1881.

WILLIAMS, J. W., major and surgeon. Paragraph 9, S. O. 2, C. S., A. G. O., relating to him, is revoked. S. O. 20, C. S., A. G. O.

BENTLEY, E., major and surgeon. Announced as acting medical director of the department until the arrival of a medical officer his senior. G. O. 2, Department of Arkansas, January 17, 1881.

GURARD, J. B., captain and assistant surgeon. To be relieved from duty in Department of Texas by commanding general thereof on receipt of this order, and then to report in person to the commanding general Department of Arizona for assignment to duty. S. O. 14, A. G. O., January 19, 1881.

TAYLOR, B. D., captain and assistant surgeon. To be relieved from duty in Department of the East by commanding general thereof on receipt of this order, and then to report in person to the commanding general Department of Texas for assignment to duty. S. O. 14, C. S., A. G. O.

TAYLOR, B. D., captain and assistant surgeon. The operation of paragraph 4, S. O. 14, C. S., A. G. O., as far as it relates to him, suspended until March 1, 1881. S. O. 20, C. S., A. G. O.

GARDINER, J. DEB. W., captain and assistant surgeon. Relieved from duty at Camp Huachuca and assigned to duty at Fort Mojave, Arizona Territory. S. O. 7, Department of Arizona, January 15, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the society will be held on Monday next, February 7th, at eight o'clock, in the hall, 19 Boylston Place. Reader, Dr. Forster. A. T. CANOT, *Secretary*.

BOOKS AND PAMPHLETS RECEIVED. — A Practical Treatise on the Medical and Surgical Uses of Electricity. By George M. Beard, M. D., and A. D. Rockwell, M. D. Third Edition. Revised by A. D. Rockwell, M. D. With nearly two hundred illustrations. New York: William Wood & Co. 1881.

Laparotomy and Colotomy, with Formation of Artificial Anus for Obstruction of Intestines. By William A. Byrd, M. D. (Reprint.)

Extripation of Rectum without destroying the Sphincter Ani Muscles. By William A. Byrd, M. D. (Reprint.)

Original Articles.

JOHN HUNTER AND HIS PUPILS.¹

ABSTRACT OF AN ADDRESS DELIVERED BEFORE THE
ACADEMY OF SURGERY, PHILADELPHIA, JANUARY
12, 1881.

BY PROFESSOR S. D. CROSS.

Of Hunter's vast labors as an original investigator I shall not attempt to speak in detail; for to do this would carry me far beyond the limits to which I am compelled to restrict myself. A brief allusion to a few must suffice. We find that the first few years of his professional life were devoted to the study of human anatomy, of which, as might readily be supposed, he made himself a thorough master, and added certain facts to the stock of knowledge previously unknown. Subsequently he devoted a large share of the time which he was able to snatch from his practice to researches in comparative anatomy, physiology, and surgery, and to the extension, classification, and arrangement of his museum. The composition of his various treatises and the papers which he contributed to the *Philosophical Transactions* also consumed not a little portion of his time. He was the first to make known the existence of lymphatic vessels in birds, and of the communication of the air-cells of the wing-bones of birds with the air-cells of the lungs; to describe the organ of hearing in fishes; to trace the connection of the arteries in the gravid uterus with the placenta; to explain the nature of inflammation of the veins; to point out, on anatomical and physiological principles, the vast chains of sympathy existing between the different organs and structures of the body, and to perform an elaborate series of experiments upon the temperature of different animals, birds, reptiles, insects, trees, and vegetables, upon the blood, and upon man in health and disease. He was the first to interpret correctly the erosion of the stomach by the action of the gastric juice after death, an effect previously erroneously attributed to pathological conditions.

He was the author of the once famous doctrine, long current among medical men, that two diseases or two morbid processes of dissimilar nature in the same organ or in the same part cannot go on at the same time. That this theory is true to a very considerable extent is unquestionable, although it is of much more limited application than Hunter had imagined. Thus, for instance, to go no further, scarlatina and typhoid fever, phthisis and cancer of the lungs, gout and dysentery are seldom found in association, and then generally only as accidental occurrences, and not as the result of any special laws. This doctrine has a much wider range and a more practical significance in surgery than in medicine, inasmuch as it lies at the root of the treatment by counter-irritation, often so useful in chronic diseases of the joints and of other parts of the body.

Hunter's ideas of the formation of monsters, a subject which at one time engaged much of his attention, were far in advance of those of his age, and strikingly in harmony with the peculiarities of his reasoning powers and his methods of study. Prior to his investigations no attempts had been made to explain the formation of this class of beings upon physiological, philosophical, or scientific principles. Most writers regarded them as the off-spring of chance, as freaks of

nature, as proofs of the divine wrath or as effects of disease of fetal life. Even the theories of Huber and Malacarne, propounded so late as the middle of the last century, were more or less tinged with the superstition of the times. Hunter, from a careful survey of the subject, founded upon the dissection of different classes of animals, concluded that these beings are simply so many deviations from the established order of nature, dependent upon an arrest of development in one case, and upon an excess of development in another, and that the cause in all exists in the primordial cell, in perverted nutrition, or in a disturbance of the ordinary laws of formative action, a fact now universally admitted by teratologists. In framing this theory he did not confine himself to the investigation of animal matter, but derived important illustrations from the study of vegetable life, and even of crystals. Indeed, he seldom, in the investigation of any subject that concerned the phenomena of life, whether in health or in disease, limited himself to the animal kingdom. His capacious mind took a higher view of things, and embraced every variety and form of organic structure. In his principles of surgery he attempts, in several places, to establish a connection between animal and vegetable pathology. He refers more especially to the changes induced in the oak leaf, and endeavors to deduce from these changes illustrations in support of his theory of inflammation. Again, in his experiments on heat, he requests Jenner to ascertain the temperature of trees and plants; and in speaking of sympathy, he remarks that "the most simple sympathy is perhaps to be found in vegetables, these being much more simple than the most simple animal."

Vegetable pathology had made too little progress, if indeed it had any existence at all, in Hunter's day to enable him to grapple with a subject of such vast proportions. It is, in fact, only recently that the subject began to attract the attention of scientists, and it was, therefore, not without the deepest interest that I listened, along with many other medical men, for upwards of an hour, to the admirable and masterly address of Sir James Paget, on *Elemental Pathology*, delivered in the pathological section of the British Medical Association, at the annual meeting in Cambridge, August, 1880. In this address are adduced numerous examples of changes induced in trees and plants by injury and disease, and of the close resemblance which these changes bear to many of those that are witnessed under similar circumstances in man and other animals.

Color-blindness attracted his attention, and he induced Jenner to investigate the matter experimentally. He was the first to describe accurately the gubernaculum of the testis. In a word, it is difficult to say what he did not do or discover. His treatise on the blood and on the vascular system is a masterly production, composed solely from the stand-point of personal observation and experiment; and what is true of this production is equally true of his surgical writings. Every page bears the impress of original work, of patient research, of carefully conducted experiment, and of inductive reasoning. His aims as an author were of the loftiest character; he took nothing for granted, nothing on credit, but subjected everything before he made it his own to the closest scrutiny and to the most searching analysis. He was too proud to borrow knowledge from others; too independent to rely upon

¹ Concluded from page 101.

their labors. Second-hand knowledge he despised, hence we seldom find any reference in his published works to the writings of his contemporaries or predecessors. Everything that emanated from his pen was stamped with the seal of originality.

He had studied the habits of hibernating animals, and from these and other considerations was led to believe that animals might be frozen and then again brought to life, and he thought the operation might be extended to the human subject; that a person might be frozen, lie in an unconscious condition for an indefinite time, even for a hundred years, and then be resuscitated. He even dreamed that the scheme, if successful, might enable him to make his fortune! How this Rip Van Winkle affair terminated never transpired.

It is not a little surprising, when one reflects upon Hunter's philosophical mind and his keen perceptive and reasoning powers, that he should have entertained such very crude notions respecting the origin of life, insisting that life is not the result simply of organization, but of something superadded to animal and vegetable matter, not unlike electricity. Every scientist of the present day knows that life is inherent in organic matter, that all growth, animal and vegetable, is inseparable from cell development, — *omnis cellula e cellula*, — and that life, as such, has no independent existence. That such very odd ideas should have floated through the brain of the founder of scientific surgery is, I repeat it, strange enough, and yet they may perhaps be pardoned when we reflect that he lived in an age when science, properly so-called, had as yet made no satisfactory advances, when, in fact, it was still slumbering in its cradle; but that John Abernethy, one of his most brilliant and intelligent pupils, and one of the most able interpreters of his doctrines, should, a quarter of a century after the death of Hunter, have indorsed and publicly defended those views, is one of those curious anomalies which are beyond our comprehension, and yet such as every one acquainted with the history of his career knows to have been the fact.¹

It was the indorsement of this peculiar notion of life, and of its existence apart from organization, that led to the sad controversy between Abernethy and Lawrence, who strenuously supported the opposite view, now universally admitted by all scientists and philosophers.

Although Hunter was an incessant worker, he derived a vast deal of aid in the construction of his museum from his assistants; indeed, without their help, it would have been a comparatively meagre affair. His pupils and intimate friends also made important contributions.

In order to show the high estimate which is placed upon the Hunterian Museum by the British Government, in a national point of view, as a nursery for the

study of biology in its widest sense, it is only necessary to state that its Board of Trustees consists of the highest officers of the Crown, including the Prime Minister, and of the President of the Royal Society, the President of the Royal College of Surgeons, and the President of the Royal College of Physicians, together with many distinguished citizens representing the more exalted walks of life. The Royal College of Surgeons, which is the custodian of the Museum, was incorporated by royal charter in 1800, and is governed by a council consisting of twenty-four Fellows, whose president in 1880 was Mr. John Eric Erichsen, the distinguished surgeon. What is called the Court of Examiners consists of twenty Fellows, whose duty it is to investigate the claims of all such candidates as may from time to time present themselves for admission into the College. Until recently no provision had been made for examinations in medicine, which now, very properly, hold a prominent place. The College, as will thus be perceived, is an immense corporation, of vast influence, binding all the surgeons in England in one great brotherhood, and virtually having charge of the educational interests of the surgical profession, as the Royal College of Physicians has of the medical.

To form anything like a correct idea of the extent of the Hunterian Museum, and of the work that is done by the College of Surgeons for its increase and preservation, it is absolutely necessary to visit it, and to spend not days but weeks, and even months, in the examination of its vast riches. The collection, in its present form, is a vast storehouse of specimens of anatomy, human and comparative, histology, physiology, morbid structure, plants, and fossils, of which nearly fourteen thousand were originally supplied from the Hunterian collection at the time of its purchase by the Government. The specimens are all classified and arranged in the order of their affinities, and are in the most perfect state of preservation, many of them being upwards of one hundred years old.

Catalogues of the museum were prepared many years ago by Professor Richard Owen and Mr., now Sir James, Paget, the latter having charge of the pathological specimens. The first curator, or, as he is styled in England, conservator, of the museum was Mr. William Clift, Hunter's last assistant, who held the office from 1800 to 1842, when he was succeeded by Professor Owen, who, in 1856, gave way to Mr. Quekett. The present incumbent is Professor William H. Flower.

Not the least interesting feature of the college is the long list of portraits of distinguished Fellows and of English surgeons of prominence a short time anterior to the establishment of the college, as John Banister, William Cowper, William Cheselden, Percivall Pott, and John Hunter himself. Among the more recent ones are those of William Blizard, Anthony Carlisle, Caesar Hawkins, George Guthrie, Samuel Cooper, William Lawrence, and William Ferguson. Among the busts which grace the halls of the college may be enumerated those of Abernethy, Everard Home, Cline, Dalrymple, Arnott, Travers, Charles Bell, Liston, Lawrence, Green, and Brodie.

When John Hunter retired upon the active duties of his profession very little accuracy had been attained in the study of medicine, or in that of natural history, in any of their branches. Linnæus had published his *Systema Nature* and his classification of plants; Mor-

¹ "Mr. Hunter," says Mr. Abernethy, "was convinced that life was not the result of organization, and, though many have conjectured life to be something not dependent on structure, Mr. Hunter was the first to deduce the opinion, as a legitimate consequence of legitimate facts, that life actually constructed the very means by which it carried on its various processes, and that it could operate in solid and even fluid substances. His intelligent mind further perceived that no system of physiology could be perfect that did not equally explain the morbid as well as the healthy actions of life. I may say that he discovered a vital principle in physiology active in producing a correct pathology. Therefore he appears to me as a new character in our profession, and, briefly to express his peculiar merit I may call him the first and great physiological gist, or expositor of the nature of disease." (Hunterian Oration for 1819, page 28.)

gagni had issued at Venice his masterly treatise on morbid anatomy, entitled *De Sedibus et Causis Morborum*; Albert von Haller was busily engaged upon his immortal work on physiology, and Buffon had given to the world the first five or six volumes of his equally immortal work on natural history. Comparative anatomy was in an embryonic condition, and pathology was rocking to and fro in the brains of Gaubius, De Haen, and Van Swieten. Science, properly so termed, that is science in its largest and widest sense, was without a master. Joseph Priestley, in 1774, discovered oxygen, or dephlogisticated air, as he called it, and along with Black, of Edinburgh, and Lavoisier, one of the victims of the French Revolution, laid the foundation of scientific chemistry. Borden and Carmichael Smith foreshadowed the advent of general anatomy, which, under the plastic genius of Xavier Bichat, at the close of the century, became a new branch of study, and a powerful element of scientific progress, under the name of histology, by which it is now universally known. The microscope had as yet no scientific significance, or any definite use as an instrument capable of elucidating healthy and morbid structure. Surgery in England at the commencement of Hunter's career, as well as for a long time after, was at the lowest possible ebb, sterile, and, as intimated in a former sentence, strongly scented with the odor of the barbershop. Of works on medicine there were none worthy of the name, and medicine itself was, if possible, in a more degraded condition than surgery. England had not one solitary medical college, and in the few private schools which then existed in the metropolis, the teaching was of the poorest and most limited kind. Bromfield, at St. George's Hospital, embraced anatomy and surgery in a course of thirty-six lectures; Nicholls, a man of note in his day, contented himself with a nearly equal number of lectures on anatomy, physiology, pathology, and midwifery; and Nourse, in 1748, at St. Bartholomew's Hospital, taught "*totam rem anatomicam*," in twenty-three lectures, hardly as many as the modern teacher devotes to the description of the skeleton. The surgical lectures of William Hunter, at his school in Great Windmill Street, could not have been conducted on a large scale. He was a great anatomist but no surgeon. It is difficult for any one at the present day to believe that no distinct or separate professorship of surgery existed in the University of Edinburgh, so renowned as a seat of medical education, until 1831, when the chair that has since existed was created for Mr. Turner. Up to that time surgery was taught by Monro, the third, merely as an appendage to anatomy, in a few hurried lectures, towards the close of the session. The labors and investigations of John Hunter formed the dawn of a new era in surgical science; he touched the corpse with his magic wand, and it sprang, like a young Hercules, to its feet; and what he accomplished for his specialty, William Hunter accomplished for midwifery, and William Cullen for medicine. These three men, all Scotchmen by birth, became the medical luminaries of their day, and the founders, respectively, of scientific surgery, scientific midwifery, and scientific medicine; in a word, the creators of a new epoch in the branches of medicine to which they respectively devoted their time, their talents, and their genius. Each labored zealously to advance our knowledge and to place his specialty upon a sure, solid, scientific foundation. They fertilized and vitalized everything they touched.

Of the 13,682 specimens which adorned his collection at the time of his death, it is safe to say that at least one fourth were prepared with his own hands. He dissected more than five hundred species of animals, and of more than three hundred of these he left more or less elaborate descriptions. During the first ten years of his professional life he was incessantly engaged in the study of practical anatomy, spending nights and days in the foul air of the dissecting-room; and in his maturer years, during which he was encumbered with a large private practice and a daily hospital attendance, he never, unless compelled by sickness, relaxed for one hour in his pursuits as an experimenter and an original investigator.

It is a remarkable feature in the life of Hunter that he should have possessed such wonderful powers of abstraction and analysis, and yet have been totally unacquainted with mathematics and geometry, a knowledge of which Plato and his school considered so essential to the full growth of the reasoning faculties. Of logic, as an elementary study, he was equally ignorant. It must not, however, be forgotten that Hunter's massive mind was cast in the Scotch mold, and that the Scotch mind is an eminently thinking mind, capable, in its higher developments, not only of the loftiest flights of fancy, but of the most patient research, of great powers of endurance, and of the most profound ratiocination.

The lesson of the life of such a man, in every respect so grand and colossal, so powerful and majestic in intellect, and so indissolubly associated with the scientific history of his age and country, is full of instruction, not only to the members of our own profession, but to men in every avenue and pursuit of life. His example of industry and of steady, persistent effort in the cause of human progress reflects the highest credit upon his character, and is worthy of the imitation of every student ambitious of distinction and usefulness. Nowhere, either in ancient or modern times, can there be found a nobler pattern for the formation of a truly scientific career. Commencing life as an erratic, hesitating youth, undecided what to do, or whither to turn, without any promise or definite aim, a source of constant annoyance to his family and of disappointment to his friends, he became eventually one of the most illustrious men in all Europe, leaving behind him imperishable monuments of patient research, of vast genius, and of wonderful philosophical acumen, destined to grow brighter and more stately as the ages roll on, and as men become more and more appreciative of man's work and of man's intellectual powers.

Nearly one hundred years have elapsed since the death of this remarkable man, this apostle of surgery, this high priest of nature. When the century shall be completed it will be a fitting act on the part of the medical world to place upon his tomb a wreath of immortelles, commemorative of the event and of the high sense of their gratitude for the services which he rendered to our profession and to mankind. Although Hunter is dead the spirit which animated him will live in all future ages to encourage and stimulate the student of surgery, of science, and of human progress. His career affords an illustrious example of a man of great intellectual powers triumphing over early defective training, and marching onward, step by step, despite vast obstacles, to the highest pinnacle of human greatness.

DIABETIC COMA; ITS RELATION TO ACETO-NÆMIA AND FAT EMBOLISM.¹

BY R. H. FITZ, M. D.

On the 13th of November, 1880, I was called to meet Dr. J. C. French, of Dedham, in consultation with regard to a patient whom he had seen for the first time on that day.

We found Mr. —, fifty years of age, lying in bed, semi-conscious, and roused with difficulty, though occasionally moving somewhat restlessly. The skin of the face and hands was of a livid hue, and warm to the touch; abundant perspiration was present on the forehead. The pupils were small, though not firmly contracted. The pulse was 140, very feeble; the respiration 40, deep and regular. Tongue and fauces dry. On auscultation the sounds of the heart were found to be normal though feeble. No abnormal sounds were heard on examination of the lungs, and air entered readily to the base of the chest. The abdomen was soft, moderately distended, neither painful nor sensitive to the touch. There was no obvious paralysis of any of the facial muscles or of those of the extremities.

The patient was evidently in a condition of coma, and there was nothing to be learned from the physical examination which could explain the severity of the symptoms.

It was learned from the relatives that Mr. —'s health had always been good, with the exception of rare attacks of indigestion and occasional difficulty of breathing, till three weeks ago. Busily occupied during the greater part of the year, he had been in the habit for many summers of spending three to four weeks in the woods, camping-out. At such times he had been troubled with boils, and comparatively slight wounds would heal with difficulty. Last summer, during his life in the woods, his health had been excellent, and he had been free from the yearly annoyance of boils. He had gained in flesh, his weight at the end of the vacation being one hundred and seventy-eight pounds.

There was no manifest cause for his present illness, which began with a loss of flesh, amounting to one pound daily. This loss was not associated at first with any notable diminution of strength, nor did it cause any immediate anxiety. It was observed that he passed more urine than usual during this time, rising two or three times at night for this purpose. He had called attention to a peculiarly agreeable odor which this secretion presented.

As the emaciation continued a loss of strength became noticeable, and on the 6th of November, from the increasing weakness, he ceased to attend to his business. At this time the attention of his nephew was called to his condition, and dryness of the skin and mouth was complained of. This gentleman suggested that the affection might prove to be diabetes, and the advice of a relative, a physician living at some distance, was sought.

During the three days immediately following the withdrawal from business there was a rapid loss of strength, compelling the patient to take to his bed. He then began a restricted diet. On the night preceding the day of my visit he suffered from frequent vomiting, which kept him awake during the greater part

of the night, and in the morning his exhaustion was extreme. Although he then recognized those about him when spoken to, he would immediately after fall into a doze. At this time his breathing was noticeably increased in rapidity, and a dusky hue of the skin became apparent. The vomiting continued during the forenoon, though the quantity raised was small, and presented a coffee-grounds appearance. He passed no urine during the day, and his bowels had not been moved for a week.

Death took place quietly in the evening, an hour after he was seen by Dr. French and myself.

Our opinion at the time was that the case was most probably one of diabetic coma, there being no evidence of the presence of any of the usual causes of coma, and the history of the case rendering the diagnosis of diabetes not improbable.

An autopsy took place on the 15th of November, forty-three hours after death. The skin was pale except at the dependent portions where there was moderate lividity. Rigor mortis was present. The head was not opened. The pericardium had a normal appearance. The heart was distended and the cavities, especially of the right side, contained dark liquid blood, which was preserved for chemical examination. The blood presented a peculiar sour odor, which was compared to that of stale lager beer. The valves of the heart were not abnormal, and the muscular substance showed no unusual appearances. The larger pulmonary arteries contained liquid blood.

The pleural cavities held no abnormal material; the pleural surfaces were besmeared with a viscid substance, readily adhering to the hands in removing the lungs. The latter organs were free from evidence of disease, were posteriorly injected and ardematous. A recent gray and slightly adherent thrombus, in which were large quantities of bacteria, was found in one of the smaller branches of the pulmonary artery. A microscopic examination of the pulmonary tissue was made with great care and at an expense of much time. A few specimens were obtained, in which a small number of fat emboli were found. Osmic acid was used to confirm the inference derived from the examination of unstained preparations.

The peritoneal cavity showed no abnormal appearances, and the peritoneum was free from any evidences of disease.

The spleen was of normal size and density, and on section was of a dark-purple color, without manifest alteration of structure.

The kidneys were of normal size, flaccid, the capsules readily detached. On section the blood-vessels were moderately injected, and the region of the convoluted tubules was somewhat opaque. On microscopic examination a slight degree of fatty degeneration and an unusually granular condition of the epithelium of the convoluted and straight tubules was observed. No distention of the renal blood-vessels with fat drops was apparent. The bladder was contracted, and contained an ounce of opaque yellow urine, which was preserved for further examination.

The liver contained a considerable quantity of dark blood, and on section emitted an odor resembling that found in the blood from the heart, though less intense.

The microscopic examination of this organ showed no abnormal appearances either in its cells or blood-vessels. It may be mentioned that numerous prepa-

¹ Read before the Boston Society for Medical Observation, December 20, 1880.

rations from the liver and kidneys were examined with and without the use of osmic acid.

The stomach and intestines showed nothing abnormal.

The negative results of the examination of the organs of the body as explanatory of the cause and severity of the symptoms is sufficiently obvious.

The chemical examination of the urine showed that the probable diagnosis made during life was correct, and that the case was one of saccharine diabetes.

The urine was acid, having a specific gravity of 1026, and was without any peculiar odor. It contained about one per cent. of albumen, and on the application of Heller's test showed the presence of sugar.

The blood was kept in a covered glass vessel for twelve hours, and was then found to have become separated into two portions; the upper fourth was of an opaque, dirty, reddish-gray color, with a yellowish layer, a line in thickness, separating it from the lower portion, which was of a dark red color. The blood was fluid throughout.

On microscopic examination the upper stratum was found to contain minute fat drops, and occasional large granular corpuscles. In the yellow border line were found numerous white blood corpuscles containing granules and fat drops. Free fat was also found in the lower three-fourths, likewise fatty and granular white blood corpuscles, with occasional large, irregular, and somewhat polygonal fatty granular corpuscles. The highly refractive granules and drops contained in the blood, and which were assumed to be composed of fat, were dissolved by means of ether. The blood was then given to Professor Wood, of the Medical School, with the request that the presence of acetone might be sought for. The following is his report:—

"The blood received from you some time since was analyzed for acetone by distilling it after the addition of tartaric acid, rectifying the distillate, and distilling the product over calcic chloride and potassic carbonate successively. In several of the distillates an odor resembling that of acetone could be distinctly perceived, although mixed with the odor of organic matter. The final product treated with bisulphite of sodium gave crystals similar to those of bisulphite of acetone."

The termination of cases of saccharine diabetes in the manner suggested by the description of the case here recorded has long since been noticed. It is also well known that diabetic patients readily succumb to intercurrent attacks of acute disease, especially of pneumonia. Under such circumstances the symptoms are not unfrequently so startling in their features and severity as to be regarded as independent of the special form of secondary disease, and out of all proportion to the extent of the lesions subsequently discovered. Such symptoms at one time were considered as the manifestations of uræmia, from their resemblance in certain respects to the closing stages in many acute and chronic diseases of the kidney. This view seemed to be favored by the frequent occurrence of albuminuria in diabetes, and the not uncommon discovery of various degrees of fatty degeneration of the renal epithelium.

Kussmaul¹ calls attention to the lack of identity of the symptoms of uræmia and those attributable to the conditions present in diabetes. He lays special stress upon the dyspnoea which is more severe in the latter affection, and is associated from the outset with open-

air passages. In uræmia, on the contrary, there is accompanying evidence of fluid in the lungs. Attention is also called to the frequency of stertor in uræmia, while this symptom is rare in diabetes, even just before death take place. The frequent and extreme uneasiness which precedes the comatose condition in diabetes is not so evident in the uræmic condition, and the pulse in the latter tends rather to become slow than rapid, as is the case in diabetes.

Other features might be mentioned which are met with in uræmia rather than in diabetes, as headache, dilated pupils, and œdema of the arachnoid.

Kussmaul first made use of the term diabetic coma as calling attention to an essential symptom, which was thus characterized as distinct from uræmic coma. He has also endeavored to learn from experiments what may be the exciting cause of the peculiar symptoms observed.

It was suggested by Dusch, in 1851, that a decomposition of the sugar in diabetes might give rise to the immediately fatal symptoms, which he recognized as distinct from those occurring in uræmia. Three years later Petters, having previously noticed a peculiar odor of the urine and other excretions of diabetic patients, compared by him to that of chloroform, found acetone in the blood and urine of a diabetic patient who had died comatose. He attributed the odor and the final symptoms to a poisoning with this ingredient. Kaulich, in 1860, further investigated this subject, and considered it essential that in diabetes a ferment should be produced in the stomach, which should cause a fermentation of the sugar, and by absorption of the products of this fermentation the symptoms of acetonæmia were considered to arise. These symptoms, as recorded by Kaulich, differ somewhat from those met with in the diabetic coma of Kussmaul, and are stated to occur in other diseases than diabetes. In typhoid fever, malarial poisoning, variola, measles, and cancer of the stomach, the odor of acetone was found in the excretions, and in consequence, certain of the symptoms occurring in those affections were grouped with those observed in diabetes, where the odor of acetone was present, under the term acetonæmia. Since then there have been contributions to the literature of this subject by Betz, in 1861; Cantani, in 1867, and others whose names will appear later.

Kussmaul made a series of experiments to determine the effect of the introduction of acetone into the blood. His results were not opposed to the theory of acetonæmia as a possible condition, although its symptomatology needed to be discovered. He considered that for its acute spontaneous occurrence in man, very large doses of acetone were necessary, and that no great accumulation was possible, owing to the rapid elimination of this substance by the lungs. It was regarded as more plausible that the continued reception of acetone in the blood, where the nervous system was enfeebled, might produce a chronic poisoning, and that the latter might assume a sudden acute course like the termination of chronic alcoholism in delirium tremens. The cause of diabetic coma, however, was to be sought for in some other agent than acetone, and in one whose nature is uncertain, although its production is to be regarded as dependent on the disturbances taking place in diabetes.

The theory of acetonæmia thus being regarded as insufficient by so eminent an authority as Kussmaul, renewed attention has been called, of late years, to the

¹ Deutsches Archiv für Klinische Medizin, 1874, xiv. 1.

possibility of discovering an efficient cause for diabetic coma. Numerous chemical examinations of the secretions, especially of the urine, have been made, with the hope of isolating some ingredient whose introduction into the body might produce the symptoms in question.

Gerhardt, in 1865, first called attention to the fact that the urine of diabetic patients which contained acetone became of a reddish-brown color when a solution of ferric chloride was added. It had already been discovered by Genther that a substance called by him athyldiacetic acid acted similarly with ferric chloride. He also found that this substance, now called aceto-acetic ether, became readily decomposed into acetone, alcohol, and carbonic acid. Gerhardt therefore suggested that the acetone present in the urine of diabetes arose from the decomposition of this aceto-acetic ether.

Soon after the publication of Kussmaul's article, with the suggestion that the poisonous agent in diabetic coma was not acetone, but some unknown agent. Rupstein,¹ who had been examining the urine of a diabetic patient with the ferric chloride test, endeavored to discover the presence of aceto-acetic ether in this secretion. He found that the color-reaction was destroyed by the addition of muriatic acid, and the application of heat; that it did not take place if the fresh urine was boiled for half an hour, at which time the odor of acetone was developed. It was also noticed by him that when urine had been kept for one or two weeks the color-reaction could not be obtained. Since only aceto-acetic ether when added to urine acts in the same way, it was inferred that this ether was present in such urine of diabetic patients as gave the color-reaction with ferric chloride. This inference seemed to be confirmed by the discovery of acetone and alcohol in the urine of the same patient. He further states that he isolated from the urine, with the aid of acetic acid and ether, a body which gave a brown color when acted upon by an ethereal solution of ferric chloride.

Fleischer² endeavored to learn whether the introduction of aceto-acetic ether into the circulation would give rise to the symptoms in diabetes which had previously been attributed to acetone.

In experimenting on dogs and rabbits with what were considered to be quite large doses no serious disturbance was noticed. The odor of the ether was detected in the breath but was not present in the urine. He took two grams of the ether internally on different days without any resulting disturbance, neither was acetone present in the urine, nor did this secretion give the color-reaction with ferric chloride. It was, therefore, considered that there was no injurious effect from aceto-acetic ether, and that this substance is partly eliminated in the organism and partly decomposed.

Fleischer furthermore opposed the view, hitherto presented, that the change in the color of the urine on the addition of ferric chloride was due to the presence of aceto-acetic ether, and that acetone in the urine arose from the decomposition of this ether. He agreed with Rupstein in the statement that heat destroys the substance in the urine of diabetes which causes the color-reaction with ferric chloride. He found, on the other hand, that the application of heat to aceto-acetic ether caused its distillation as such, with the retention of the property of becoming reddish-brown on the addition of ferric chloride.

Fermentation destroyed the coloring property of

aceto-acetic ether, while the fermented urine of diabetes still became characteristically colored when the iron test was used. When corresponding degrees of color were produced in the urine of diabetes and in normal urine mixed with aceto-acetic ether, the former gave out no odor of the ether, which was evident in the latter mixture.

The results of these experiments were therefore regarded as justifying the conclusion that it is questionable whether aceto-acetic ether is present in the urine of diabetic patients.

Fleischer was able to discover acetone and alcohol in the urine of the cases of diabetes examined by him, even when no color-reaction resulted from the use of ferric chloride. The acetone was the more abundant the longer the urine had been passed. The presence of aceto-acetic ether being in doubt, he offers as a suggestion for the formation of acetone that it represents the product of a fermentation of the sugar in consequence of the presence of a specific acetone ferment. The ferric chloride test is considered to have a certain practical value as it gave no reaction when added to the urine of mild cases of diabetes, and may thus be regarded as indicating the more severe forms.

The latest contribution to the chemistry of this subject comes from Quinke.³ He determined the amount of the material present in the urine which gave the reaction with urine, by comparing the resulting color with that obtained from a standard watery solution of aceto-acetic ether. Four parts in a thousand were found to represent the daily average for a month, which corresponded with six to eight grams of excreted substance. He noticed that there was no odor of the ether in the urine, although an artificial solution of one part of the ether to one thousand parts of water presented a characteristic odor. At the same time he noticed that when aceto-acetic ether was added to the urine of his patient it met with a loss of odor, which was not the case when it was added to normal urine. Quinke is inclined to admit that the substance in the urine reacting with ferric chloride is not simple, soluble, aceto-acetic ether.

From the subcutaneous injection of four cc. in rabbits, a dose twice as large as that used by Fleischer, there resulted restlessness, stupor, and difficult and accelerated respiration, frequently terminating in death. Five to ten cc. were necessary to produce death in dogs, and urine taken from the animals immediately after the injection gave a reddish-brown color with ferric chloride. The effect of the introduction of the ether was by no means uniform; for in certain cases death occurred without dyspnea, and glycosuria was instantaneously observed. It was also obvious that the ether rapidly decomposed, from the fact that the urine only occasionally gave the color reaction with iron, — and then but for a short time, — and that its odor was never perceived in the breath.

Quinke suggests that, as all the reported cases of diabetic coma do not present the same group of symptoms, it may be that several substances are found in varying quantities. Their cumulative, poisonous action may then take place, as in uramic coma, without any single ingredient being alone in question.

Cases of diabetic coma have recently been published in England by Dr. Foster⁴ and Dr. Southey.⁵ The

¹ *Centralblatt für die med. Wissenschaften*, 1871, lxxv., 865.

² *Deutsche med. Wochenschrift*, 1879, volume 218.

⁴ *The British Medical Journal*, 1878, 78.

⁵ *The Lancet*, 1879, 192.

acetonæmic theory is adhered to by both these writers, without, however, any new evidence being presented.

Dr. Foster claims that the addition of acetone to blood produced the gross and microscopic appearances found in the examination of the blood from his patient.

During the past year the question of the origin of diabetic coma has been considered from a new point of view. Drs. Sanders and Hamilton,¹ being dissatisfied with the theory of acetonæmia as a cause, thought that the fatty condition of the blood, frequently noticed in diabetes, might give rise to fat-embolism, and thus mechanically produce the dyspnoea.

The examination of the blood of two patients showed the presence of fat, and in one an extensive fat-embolism of the pulmonary blood-vessels was found.

Fat drops were also discovered in the blood-vessels of the kidneys and liver of this patient. The odor from the blood of one patient was like that of acetone, and a trace of acetone was observed in the blood of the second patient.

The discovery of the evidence of fat-embolism associated with lipæmia, and the analogy in the dyspnoea and coma from fat-embolism following the fracture of bones with these symptoms observed in diabetes, led Sanders and Hamilton to advance the theory above mentioned. They were further influenced by the view that the quantity of acetone found in the blood of diabetic patients seems too small to account for the fatal symptoms, and that the effects of poisoning with acetone rather resemble those due to alcohol. They were unable to confirm the statement of Dr. Foster that the addition of acetone to blood produces appearances resembling those found in the blood of diabetic patients.

Dr. Starr² gives the report of a case of diabetes with lipæmia and fat-embolism of the lungs. The patient had pneumonia, and it is stated that there was no perceptible odor of acetone during life or at the post-mortem examination. On the contrary, in a case of diabetic coma reported by R. V. Jacksch³ the blood was examined during life for fat drops, with a negative result. The color-reaction with ferric chloride was obtained, and ether is said to have extracted from the urine acidulated with sulphuric acid the material whose presence occasioned the reddish-brown color. Distillation of the ethereal extract caused a gradual disappearance of this reaction.

It is evident, from what has been stated with regard to the chemical examination of the blood and urine in diabetes, that no ingredient has been found whose presence is sufficiently explanatory of the nature and severity of the symptoms. It also appears not unlikely that modifications in the composition of the blood are present, and that the severe symptoms, if not the fatal result, are often due to a poisoning with one or more agents, which alone, or in combination, represent the efficient cause.

The case here recorded opposes the theory of fat-embolism as the cause of the coma; for neither in the blood nor in the blood-vessels of the viscera was any considerable quantity of fat found. Additional evidence in this direction is furnished by the case reported by Jacksch.

It is also manifest that in fat-embolism resulting from the fracture of bones dyspnoea and coma are by

no means constantly present; although it is probable that in most, if not in all, cases of bone-fracture and crushing of fat-tissue a lipæmic condition results.

It seems quite probable that the fat found in the blood-vessels of Mr. — may represent the result of an absorption of fat as indicated by the rapid emaciation mentioned in the record of symptoms.

In one of the cases reported by Sanders and Hamilton the statement of the progressive emaciation of the patient is recorded, and it is well known that it is the rule for diabetic patients, who are seriously ill, to become progressively emaciated.

It is also not improbable that the lipæmic condition, when present, may in part be the result of a fatty degeneration of the white corpuscles of the blood, or of the endothelium of the vascular wall, — a view suggested by the appearances found in the microscopic examination of the blood. Too little attention has been directed to the possibility of an embolic lipæmia in other emaciating diseases than diabetes, — a subject which certainly demands investigation in consequence of the interesting discovery made by Sanders and Hamilton. My own inability to confirm their observations in degree does not detract from their value, but necessitates the conclusion that a theory of exclusive origin of diabetic coma based upon the discovery of an embolic lipæmia is not probable.

It is further evident that continued experiments are desirable with regard to the action of acetone, acetoacetic ether, and the ethereal extract from acidulated urine of diabetic patients. The differences in statement with reference to the chemical properties of the latter make it manifest that further investigation in this direction is demanded.

It may be stated in conclusion that it is probable that the condition called diabetic coma owes its origin to several causes, chiefly chemical and partly mechanical. All of these are not likely to be constantly present; nor, when present, are they necessarily in the same ratio.

In consequence of such variations in the nature and proportion of the efficient causes, certain differences in results are likely to follow. For the present it is convenient to include these, from the predominant symptom, under the descriptive term of diabetic coma.

GYNECOLOGY IN NEW YORK AND BROOKLYN.

BY W. H. BAKER, M. D.

At the College of Physicians and Surgeons, the work in this department, in charge of Dr. T. G. Thomas, continues from October 1st to May 1st, and consists of a didactic lecture each Monday, at five o'clock, P. M., and a clinical lecture each Tuesday, at three P. M. The material for the latter lectures is supplied from an out-patient department for the treatment of the diseases of women, which is in the college building, open throughout the year, and carried on by assistants of Dr. Thomas. One of the hours of attendance thereat immediately precedes the hour of his clinic, and two, three, or more cases are detained and ushered singly into the lecture room as required. Here the patient is given a chair where she sits with bonnet and shawl on while she is questioned by the lecturer, and the prominent points in the case thus brought out, an outline of it,

¹ Edinburgh Medical Journal. 1879. cclxxxix. 47.

² The Medical Record. 1880. 477.

³ Centralblatt für die med. Wissenschaften. 1880. xlviii. 889. Prager Med. Wochenschrift. 20 and 21. 1880.

together with the diagnosis, having previously been furnished him by the assistant. The professor then gives a short clinical discourse on the particular disease or condition of the patient, which he often illustrates by use of the blackboard, by diagrams, and by a most ingeniously contrived manikin constructed by himself and figured in the last edition of his valuable work.

The most advanced students and the post-graduates are invited in sections of ten each to attend his operations at the Woman's Hospital. No instruction in the education of the touch is given, it being found impracticable in so large a school, numbering something over five hundred and fifty students, to furnish facilities for individual examination of cases. The student here is most fortunate in listening to the unequalled lectures of Dr. Thomas, able, interesting, and instructive; but his clinical advantages are necessarily limited and his opportunities for practical work almost nothing.

Since the death of Dr. Peaslee, the department of gynecology at Bellevue College has been associated with that of obstetrics, under the charge of Dr. Lusk, whom we remember well as a lecturer on physiology, when some of us were students at Harvard. It was a pleasure to see his familiar face again. He has lost none of the earnestness, ability, or zeal which always characterized his teachings.

The course here continues twenty-four weeks, beginning October 1st. Sixteen didactic lectures are given in the college building on Saturday mornings at nine o'clock. Each Wednesday at the same time, in the Bellevue Hospital building, a clinical lecture is given, which is illustrated by an operation or by the exhibition of a patient, when the students have an opportunity of seeing the exact local condition. This exercise is placed at an hour when some other lecture is in progress, and only those students who have passed their examinations in anatomy are admitted. The lectures are still further illustrated by diagrams, charts, and the use of the blackboard.

On Thursdays, at half past one, there is an exercise in the hospital amphitheatre which, after January 1st, partakes quite of the nature of a clinical conference. It is open to the whole school, but only the most advanced students are allowed to take part in it. A student has a case assigned him from the ward, of which he takes the history and makes an examination, writing it out in full. This he reads at the conference and is questioned by the professor. The class being large, no one student is called upon more than once during the term. Or if there are one or more cases in the ward which can be readily diagnosticated, they are brought before the class and one of the most advanced students is called upon to examine and make a ready diagnosis. This Thursday exercise is termed by Dr. Lusk his diagnosis class. Before January 1st, and until the students have become somewhat familiar with the subject, it is more nearly in its character, a clinical lecture.

The advantages which the students of this school have for acquiring familiarity with the appearances of acute cases of uterine disease are very great. With the exception, however, of the times when one or another student is asked to examine a case, he has few opportunities to educate the touch. The clinical advantages are given alone to the most advanced students.

By the kindness of Dr. Skene I was invited to visit Long Island Medical College. This institution is immediately connected with the Long Island Hospital,

and the department of gynecology, entirely distinct from that of obstetrics, is most faithfully and ably cared for by Dr. Skene. The regular course begins February 1st, and continues until the latter part of June. During this time there is given each Monday at eleven a didactic lecture, and each Tuesday at two a clinical lecture. At this latter exercise, if the case be one requiring operative interference upon the external genital organs, so that it is practicable for many students to witness it, the operation is done before the class. Or, on other occasions, the professor reads the history of a case and calls upon a student from the class to examine it in an adjoining room. On his return to the lecture room, he is questioned by Dr. Skene, who subsequently lectures upon the case, in regard to the condition found and the diagnosis made. These clinical exercises are also held throughout the preliminary course, which extends from October 1st to February 1st. We understand it to be the future intention of the college to unite the two courses, preliminary and regular, making one regular course of seven or nine months. The material for the clinical lectures is furnished either from the gynecological ward of the hospital or from the out-patient department of the hospital in charge of two assistants of Dr. Skene. The facilities at this school for the students to practice the touch and to become otherwise familiar with the appearances of uterine disease are undoubtedly superior to those of any other school in this vicinity. The whole number of students being much less than in the colleges of New York, it becomes possible to take the advanced ones by sections of from three to five each into the out-patient department, where the assistants in charge instruct them in the touch, etc.

Through the courtesy of Dr. Pallen, I was shown the workings of the department of gynecology at the University of New York. The season is about twenty-four weeks in length, and during that time Dr. Pallen lectures each Thursday at half past one o'clock, the lecture being clinical in its character and based upon two or more cases furnished from the out-patient department for the purpose of illustration. The patient is rolled in upon a table, covered, and after reading a short history of the case, the sheet is thrown back from the lower part of the body, and the patient is shown to the class, which at this exercise averages about three hundred and seventy-five in number. If it be an operative case, as laceration of the cervix uteri, rupture of the perineum, etc., Dr. Pallen operates before the class, and there being no hospital in which to place the patient subsequently, she is taken to her home in a carriage, and looked after by one of Dr. Pallen's assistants. This whole method seemed to us to savor of severity to the patient. In regard to successful recoveries, we were assured by the professor that the results have been most satisfactory. In so large a class very little can, of course, be seen save by the few students immediately behind the operator. Still there is considerable advantage in becoming familiar with the different positions of the patient on the table for examination, treatment by operation or otherwise, and to a certain extent the broader manipulations of the operator are observable. The clinical material is furnished from the out-patient department kept up in the college building for the purpose, and in charge of Dr. Pallen's assistants. The number of new patients received here annually is about one hundred and fifty, being quite sufficient to supply illustrative cases for the weekly

lecture. The advantages to the student at this school for practical work, the education of the touch, the attempts at diagnosis, etc., are very small. We understand it is the intention to give to post-graduate students a series of didactic lectures which shall be open to them only.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. LYMAN.

REPORTED BY DR. JOHNSON, HOUSE OFFICER.

CASE I. ABORTION; PELVIC ABSCESS; INTRA-UTERINE INJECTIONS.

ANNIE K., aged twenty-five, single, was brought to the hospital October 1, 1880, by the police in a state of stupor and great exhaustion. She had been taken from a house of ill repute under circumstances which indicated that abortion had been committed. Too feeble to give any history of herself or even to be properly examined.

October 4th. On examination, the cervix found to be bilaterally lacerated. Vagina hot and with an offensive purulent discharge. Tongue dry and heavily coated. Fæces and urine discharged involuntarily. Temperature 102° F. Pulse 112. Ordered hot carbolyzed vaginal douches three times daily; also intra-uterine douches of permanganate of potash (three grains to one ounce) thrice daily. Quinine five grains every four hours, and whisky one ounce every three hours, to be increased or diminished as needed.

Eight p. m. Masses of shreddy, offensive tissue followed the injections. Now refuses or is unable to swallow. Brandy and egg given per rectum and retained. Discharges less offensive.

October 5th. Still unable to swallow, and rectal enemata continued. Vaginal discharge more abundant and less offensive. Temperature 102° F. No extreme suprapubic tenderness. Uterus measures four inches. In the evening the patient was still extremely feeble, but somewhat brighter, and swallowing nourishment. Whisky to be given, one ounce every hour, unless excited by it.

October 6th. Some vomiting during the night. Still semi-unconscious. A round, hard, slightly fluctuating tumor is felt in Douglas's pouch. Vaginal discharge still offensive, but diminishing. Tongue clearing. Passes fæces in bed. Temperature normal. Pulse 96, and fair.

October 7th. Much the same. On giving the douche, an opening was found into Douglas's pouch admitting the tip of index finger, from which pus flowed freely.

October 8th. Brighter, and takes nourishment well. Still passes fæces in bed. Says she feels better. For the first time, owing to her extreme exhaustion, a thorough examination was made. Uterus slightly anteverted and movable; os patulous and bilaterally lacerated; depth of uterus, three and a half inches. Behind the cervix, in the posterior cul-de-sac, an opening one fourth of an inch in length, through which a probe passes downward and backward along the left side of the rectum about three inches. Through this issued

thick, creamy, but not very offensive pus. Sac to be injected three times a day with permanganate of potash.

October 10th. Brighter. Answers questions, calls for bed-pan, and asks for increase of diet.

October 13th. Vomits occasionally, but is in every respect better. Complains of some headache and ringing in ears from the large doses of quinine. Says she was confined a year ago at Lying-In Hospital under assumed name. Is unable or unwilling to give any satisfactory account of her recent history before entering hospital.

October 17th. Large amount of pus washed out of uterus and posterior cul-de-sac. Although she vomits occasionally continues to improve. Stimulants diminished.

October 18th. Pus continues free, but odorless, from both uterus and sac. In afternoon had an access of pain in abdomen and rising temperature (103.2° F.). Hot fomentations and carbolic-acid douche in place of permanganate.

October 19th. Temperature 102° F. Pulse quick and feeble.

October 23d. Under the use of fomentations, quinine, opiates, douche, etc., the acute symptoms have disappeared. Has now no pain and but little discharge. Ordered tincture of chloride of iron in place of quinine.

October 24th. Uterus now measures three inches.

November 7th. Has steadily improved, though with many alternations as to pain, vomiting, and amount of pus discharged. After use of douche this morning had several well-marked convulsions, followed by unconsciousness and feeble pulse for an hour or two, during which time she had ether and brandy subcutaneously and stimulating enemata.

November 8th. Is again quite comfortable, yesterday's attack being partly hysterical.

November 10th. Menses appeared.

November 27th. Patient has steadily gained, though there is still some purulent discharge from the cul-de-sac. Dilated the opening and applied tincture of iodine freely to walls.

November 29th. No discharge for twenty-four hours.

December 8th. Left hospital, well, except for a trivial discharge from cul-de-sac.

This patient, when first admitted, seemed almost moribund, and though powerfully stimulated, the reaction was very slow and unsatisfactory. The result may fairly be attributed to the quinine, the constant and persistent use of intra-uterine injections, and the unremitting attention to the case, night and day, of the attendants.

CASE II. ABORTION; PELVIC ABSCESS.

M. E. M., aged twenty, married, and mother of one child, was admitted to City Hospital November 9, 1880. States that her catamenia reappeared ten months after labor, and continued normal until their cessation, three months ago. Four weeks since took "tansy tea," which brought on a profuse flow, accompanied with pain. At the end of a week the pain and dysuria became very severe and the defecation difficult. Had abscess in the right breast, and the left breast was very tender and nodulated.

November 10th. Excessive tenderness and heat, especially in the vaginal cul-de-sac. General febrile

excitement. Ordered poultice to abdomen, hot carbolized douches, and the left breast to be strapped.

November 14th. Pain almost gone. Induration to left of the cervix, from which pus escapes freely by a spontaneous opening. Patient much relieved.

November 27th. Discharge has continued to date. Has had occasional doses, as required, of morphine and belladonna by suppository. To-day has a recurrence of high temperature and other acute symptoms. Ordered quinia in ten-grain doses, morphia subcutaneously, and poultices.

December 7th. To the right of the cervix a large mass of induration is felt. The cervix itself is quite livid, and almost obliterated by bulging of the vaginal wall.

December 8th. Aspiration of the abscess removed, half an ounce of pus and blood only, but enough to relieve the pain and tension, and she steadily improved until the 16th, when, upon examination, a small indurated spot only could be felt, which was painless on pressure.

December 18th. Was discharged, well.

CASE III. ABORTION; RETAINED PLACENTA: INTRA-UTERINE INJECTIONS.

M. C., thirty-two, married, entered hospital October 11th, pale and feeble. Confined with her third child September 12th, after two days' labor. Thinks a part of the afterbirth came away. Since confinement has had several rigors, followed by fever. Suffers from bearing-down pains, and constant hæmorrhage to the number of ten or twelve napkins daily. Vaginal discharge very offensive, and has been so, she says, from the first. No vomiting. Sleeps a great deal. Micturition frequent and difficult. Temperature 99° F. Pulse 100. Upon examination, perinæum found to be ruptured quite to sphincter ani. Vagina roomy, cool, and containing blood clots. Protruding from the os was a very offensive mass three and one half inches long by two and a half broad. Its removal was followed by free hæmorrhage. Ordered quinia, six grains every four hours, hot carbolized vaginal douches at frequent intervals, to be carried morning and evening into the uterus, with absolute rest and liquid diet.

October 12th. The mass from the cervix proving to be only blood clot, the uterus was explored, and upon the upper left side a hard body the size of a hen's egg was found very firmly attached to the walls. With great difficulty a portion was removed by the finger, and the remainder crushed and removed, so far as possible, by Emmet's forceps. Some hæmorrhage ensued, which was promptly checked by a swab of tincture of iodine. Ordered opium, hot fomentations, and fluid extract of ergot. The procedure was followed in a few hours by a severe rigor, the temperature rising to 104° F. Thirty grains of quinine were given at once, the temperature falling two degrees in three hours. Had some headache and tinnitus the following day.

October 14th. An abundant flow of pus from uterus, and night-sweats.

October 16th. Improving. Less flow of pus. To take quinine freely.

October 19th. Pus varies in quantity, but is no longer offensive. No more rigors. Complaints of headache and tinnitus. Tinct. ferri chloridi substituted for quinine.

October 23d. Much improved. Trifling discharge from cervix. No more night-sweats. Intra-uterine douches discontinued.

October 27th. Discharge ceased. Eats and sleeps well, and at her own request allowed to go home.

(To be continued.)

THE CAPACITY OF SPOONS.

BY EDWARD J. FORSTER, M. D., CHARLESTOWN, MASS.

At a society meeting a few weeks since the capacity of a teaspoon was given by one gentleman as about eighty drops, while another said that many people believed that twenty drops and a teaspoonful were equivalents.

The difference being so great I took an early opportunity to make a number of measurements of tea, dessert, and tablespoons, with the results as given below. By the "usual amount" is understood to be as much as would ordinarily be taken up, so that the spoon would be full, but yet could be moved about without spilling its contents; the "greatest amount" is as much as could *possibly* be poured in.

The apparent discrepancy in the tables whereby the ratio of the two amounts is not maintained, is accounted for by the different shape or flare of the spoons. The liquid measured was water drawn directly from the faucet.

Measurements of *teaspoons* of different patterns as found in four different dwellings:—

Usual Amount.		Greatest Amount.	
1	50 minims.	1	90 minims.
2	55	2	70

PROLONGED GESTATION.

BY C. A. WILCOX, M. D., UXBRIDGE.

Mrs. C., whose last menstrual flow commenced March 12, 1880, and continued as usual six days, gave birth January 11th to her fifth child, two hundred and ninety-nine days after disappearance of the menses, is positive she felt motions some days previous to July 26th. The labor was natural, and recovery good. The child, a girl, weighed nine and one half pounds, the largest of the five, and at two weeks looked as old as other children of a month. Mrs. C., while perfectly regular, has previously observed a full period of five weeks.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, SECRETARY.

NOVEMBER 15, 1880. DR. EDGERLY read a paper upon

A CASE OF SARCOMA OF THE KIDNEY.

The patient was a girl of seven. For several months she had fugitive pains in the left side, which attracted no attention. She then had quite a sudden onset of severe paroxysmal pain, referred to the region of the spleen and lower chest. Dr. Edgerly now saw her, and upon examination detected a slight fullness of the left side. Upon percussion a dull area was found, reaching from a point one inch below the level of the nipple in the axillary line to a little below the free border of the ribs. This dullness extended anteriorly and posteriorly about half-way to the median line. An indistinct sense of fluctuation was perceptible beneath the ribs. This region was tender to pressure or percussion. The pain abated, and for a week left the child quite comfortable. It then returned suddenly, and, a more lax condition of the abdomen allowing a thorough examination, a lobulated mass was felt reaching from beneath the costal cartilages down nearly to the level of the umbilicus and midway to the median line. This was hard below, soft, seemingly fluctuating above.

In consultation with Dr. Morrill Wyman, a brisk catbarris having failed to remove the mass, a hypodermic needle was introduced into the fluctuating portion, but only a few drops of dark blood drawn. From this time the tumor steadily increased in size and the child as steadily lost weight. The urine was carefully watched during the progress of the case, but at no time presented an unusual appearance. Death occurred in sixteen and a half weeks after the first discovery of the tumor.

The autopsy showed the mass to consist of the greatly enlarged left kidney. It extended from the nipple nearly to the pubes, filling the left side and extending somewhat into the right. Some of the lobes of the tumor resembled in color and consistence the white substance of the brain; the other portions were dark purple, much like the normal spleen in appearance.

DR. EDGERLY called attention to the difficulty in the way of diagnosis, owing to the absence of any alteration of the urine.

DR. FITZ spoke of the extreme rarity of renal sar-

coma. Monti mentions nine recorded cases, but several of these have doubtful features about them. In nearly all of the reported cases the absence of hæmaturia is especially noted, and albuminuria was present in but one case. Many of the well-authenticated cases were congenital or appeared soon after birth. This and the fact that Cohnheim has found involuntary muscular fibres in one of these growths would suggest the supposition that an inclusion of embryonic tissues had occurred during fetal development, and that these included portions had later taken on renewed growth. Without a careful microscopic examination to decide the nature of the tumor in Dr. Edgerly's case there would be grave doubts as to its character, since hæmaturia is sometimes absent in carcinoma.

DR. CURTIS mentioned the fact that Cornil and Ranvier had met with but two cases of renal sarcoma, as evidence of its extreme rarity.

DR. SABINE mentioned a case which he had seen in Strasburg in a child six or eight years old. The tumor was extremely soft, and was made up of round and spindle cells. He asked whether the youth of Dr. Edgerly's patient was not favorable to the idea of sarcoma rather than of cancer.

DR. FITZ said that the age could not be relied upon for the diagnosis, as cancer does sometimes occur in children. He asked whether the blood had been examined in the case reported.

DR. EDGERLY said that he had examined it roughly, and had found the white blood cells unusually abundant, though the exact proportion was not ascertained.

DR. CUSHING reported briefly several cases of an affection which he thought in many points similar to the epizootic prevailing among horses. In all of these patients the lymphatic glands about the angle of the jaw were enlarged and the parotids were considerably swollen. The tonsils were slightly reddened. These appearances were accompanied by considerable fever, the patients being confined to the bed often for a fortnight.

Similar cases had been seen and were reported by other members of the Society.

In answer to a question as to the amount of the glandular swelling in the horses, DR. McCOLLOM said that it was a marked feature, even in many mild cases of the epizootic.

DECEMBER 6, 1880. DR. FISHER read the regular paper on

HABITUAL DRUNKENNESS.

DR. CHANNING said that the treatment of habitual drunkards in insane asylums was inconvenient, as they were soon comparatively well, and then required careful watching.

In England from seventeen to twenty per cent. of insane cases are thought to depend on drink. Drunkenness seems to be a less common cause of insanity in America.

DR. WEBBER urged that the opinion often given by physicians that drunkenness is a disease does great harm in affording drunkards an excuse both to themselves and others for their habits.

DR. H. R. STEDMAN said that he had yet to see the case of a drunkard really benefited by confinement in an insane asylum. Their treatment involves a totally different principle from that of the really insane. In-

¹ See Boston Medical and Surgical Journal, vol. ciii. p. 632, and vol. c v. p. 3.

sane patients are better without restraint, while drunkards need it.

DECEMBER 20, 1880. Dr. FITZ read the regular paper upon

DIABETIC COMA, ITS RELATION TO ACETONÆMIA AND FAT-EMBOLISM.¹

The various chemical reactions spoken of in the paper were shown in specimens of diabetic urine.

Dr. WOOD said that he should confirm the statement of Dr. Fitz, that it is impossible to say with certainty that aceto-acetic ether preëxists in the blood and urine in these cases of diabetes, either on account of the reaction with ferric chloride or from the possibility of isolating acetone from these fluids, since other substances, such as acetates of potassium and sodium, may give the reaction with ferric chloride, and also since we are not sure that other substances than aceto-acetic ether, capable of giving acetone as a product of decomposition, may not also exist in such urine.

Thus if normal urine be so diluted with water that the normal constituents are present in about the same proportions as in diabetic urine, and a little acetate of sodium be added, the same color will be produced upon the addition of ferric chloride, as in the case of diabetic urine.

It is not probable that this reaction in the urine of diabetes is really due to the presence of an alkaline acetate, but some other substances besides aceto-acetic ether may give it.

Dr. T. B. CURTIS inquired of the reader what bodily temperatures had been observed in diabetic coma. This condition had been recognized to be very analogous to uramic coma, in which, according to Boivinville and others, the temperature is almost invariably below the normal, as in a case recorded by Bartels, where it fell before death to 83° F. It would be interesting to know whether in this respect, as in others, the two forms of coma, the diabetic and uramic, are similar.

Dr. FITZ did not recall the observations upon this point. In the case recorded no observation of temperature was made.

Dr. WEBBER mentioned a case of diabetes now at the City Hospital, in which there is at intervals a drowsy condition accompanied by nausea and vomiting. The general condition of the patient is remarkably good, considering the severity of these occasional symptoms. The urine, which at one time amounted to 7000 cc. in twenty-four hours, has diminished to 3500 cc. in the same time. Dr. WOOD said that the reaction with ferric chloride shown by Dr. Fitz was produced with the urine from Dr. Webber's case.

Dr. CUTLER asked whether the aceto-acetic ether was found in other excretions.

Dr. FITZ said that in the experiments made upon animals the odor of this substance was noticed in the breath.

Dr. S. CABOT reported the following case of partial coma, believed to be due to fat-embolism:—

A young man of twenty-four sustained a compound comminuted fracture of the left leg. There was no evidence of any injury of the head, and he was perfectly rational till the morning of the day after the accident, when he was found in a drowsy condition, taking no notice of questions. He often carried his hand to his head as if he suffered pain there, though

in partially lucid intervals he said that he felt pretty well. At night he began to pass his urine in bed. On the following morning his breathing was accelerated, and there was some lividity, but an examination of the lungs detected nothing. He remained in this condition for eight days, and then began to improve. On the tenth day (from the injury) he retained his urine, and was able to answer questions. He now complained of pain in the right side of the head. This right hemiparesis continued intermittently for two weeks, after which time he seemed perfectly well. He had no recollection of the time during which the drowsiness lasted. The process of healing in the injured leg was uninterruptedly good.

Dr. FITZ said that Dr. Cabot's case illustrated the difference between the diabetic coma, believed to be due to acetonæmia, and that caused by fat-embolism. The diabetic coma was very profound compared to that of fat-embolism, and the respiration was deep and slow, while in the case reported by Dr. Cabot it was rapid.

Dr. BAKER showed a calculus passed through the female urethra with so little pain that the patient was unaware of its presence till she heard it drop in the vessel. It was curiously twisted on itself, and measured perhaps one half by three quarters of an inch in two of its diameters, with a thickness of rather less than a quarter of an inch.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

INDUCTION OF PREMATURE LABOR ON ACCOUNT OF NARROWING OF THE ANTERO-POSTERIOR DIAMETER IN A DWARF. MANUAL DILATATION.

MAY 8, 1880. Dr. SINCLAIR read the case.

Dr. RICHARDSON stated that the operation was performed by Dr. Sinclair, and illustrates the advantage of manual dilatation. He said that he had never before seen a case in which the value of this method was so marked. The dilatation was complete in twenty-five minutes, the os had entirely disappeared, and the membranes were at the vulva, filling the entire vagina. The operation had been easily, slowly, quietly, and surely performed. With Barnes's dilatation the operation could not have been so well accomplished, even in many hours. Manual dilatation constitutes one of the most successful changes in obstetric practice, in cases in which one is called upon to deliver a woman where labor is to be brought on, no sign of labor as yet being present.

Dr. SINCLAIR stated that in primiparæ the vagina was to be first dilated just as the cervix was to be later in the process, and that it was necessary to be sure that the cervix was thoroughly tired out before beginning to turn. There was no reason, he said, why the cervix should be torn if one only took time.

Dr. RICHARDSON remarked that when one has once made up his mind he will substitute manual dilatation for all other operations whatever for bringing on labor.

Dr. Richardson stated that four out of six cases, in which he had done the operation, were primiparæ; that the time in a multipara was shorter than in a primipara; and that the general rigidity of the parts

¹ See page 124.

made a difference in the time of the operation. When the os was once fully dilated there came the question between version and forceps. Sometimes labor pains had occurred for the first time during the process, so that towards the latter part the uterus would be in a state of constantly recurring contraction, in such case threatening to become almost tonic. With this condition one should choose the forceps, version being almost impossible. In the majority of cases, however, dilatation has been completed without a sign of labor; but the uterus has immediately followed after the fetus, and there has been no tendency to hemorrhage.

DR. SINCLAIR observed that it was a great satisfaction to feel that one can at will empty the uterus, and stated that he had done it as early as the fifth month, on account of constant hemorrhage, in a case in which an abortionist had been passing up an instrument from time to time. In this instance the placenta was entirely adherent, and was removed with great difficulty. His first reported operation was performed January 18, 1870, on a primipara who had been in convulsions for twenty-four hours, in whose bladder was found only a drachm of urine, which became solid when heated.

HYDRATE OF CHLORAL IN CASES OF RIGID OS UTERI.

DR. RICHARDSON read the following paper:—

At the meeting of the American Gynecological Society held in New York in 1876, I called the attention of the members to the value of the hydrate of chloral for the relief of labor pains. Incidentally I alluded to its effect in one case in a patient whose labor was rendered tedious and her suffering greatly aggravated by a rigid condition of the os uteri.

Since that time I have had frequent occasion to observe the beneficial use of this drug in similar cases, in which the chief difficulty seems to consist in a rigid condition of the os uteri. The following record will illustrate its use in such cases:—

A. D., aged twenty-three, primipara. Labor began about three o'clock in the morning of January 22, 1880. I first saw the patient two hours later. The presentation was normal, the head being in the anterior variety of the first position. The os barely admitted the tip of the finger. The membranes were unruptured. The pains were severe, occurring every ten or fifteen minutes. Six hours later the os was the size of a silver quarter of a dollar, and felt thin, and as though a small wire surrounded it. The pains were present about every five or six minutes, and were very severe. Two hours later no progress had been made, and the patient was becoming restless and fretful. Fifteen grains of chloral were given and repeated in twenty minutes, and a third dose twenty minutes later. Within ten minutes after the third dose the patient began to doze between the pains, and even during the presence of a pain she would not fully arouse, but talk somewhat incoherently. An hour later, the pains seeming to distress her more, two doses of chloral (gr. xv. each) were given at twenty minutes' interval, and the patient again fell into a sound sleep, the recurrence of the pains being marked only by restlessness or moaning. The pains recurred at frequent intervals, and three and a half hours from the time the first dose of chloral was administered the os uteri was fully dilated. The membranes were then ruptured with a catheter, and the labor ter-

minated two hours later with the birth of a boy weighing seven and one half pounds. During the second stage of labor the mother became more conscious, and at its termination was fairly awake, although she soon fell into a natural sleep after the removal of the placenta and the application of the binder.

This case illustrates, what I have frequently seen, the advantageous use of chloral as an anæsthetic in cases of tedious labor owing to a rigid condition of the os uteri.

ALBUMINURIA IN REPEATED PREGNANCIES.

JUNE 12, 1880. DR. DOE stated that he had attended a lady in her fourth confinement who had suffered from albuminuria in each preceding pregnancy.

The first child was still-born at the sixth month; the second and third, born at the seventh month, lived respectively five and twenty-four days; the fourth at seven and a half months, lived seven weeks. In the second and third pregnancies, delivery was followed by a single convulsion. There had been with each pregnancy marked œdema and general anasarca, attended with impaired vision and scanty urine.

In the last one she was confined to bed for a week before delivery on account of excessive swelling of the feet and extreme dyspœa on exertion. She was unable to recognize a person across the room. The urine measured about one pint daily, under the use of diuretics, and was heavily loaded with albumen, but contained very few granular and hyaline casts. Just previous to the commencement of labor she passed a gallon of urine, and the delivery was rapid and unattended by any abnormal symptoms. The albumen quickly disappeared; but the impairment of vision had not wholly subsided seven weeks later, when she left the city.

Between her pregnancies she had no symptoms pointing to renal trouble, and considered herself perfectly well.

DR. HOSMER inquired as to the condition of the eye which determined the blindness.

DR. FORSTER stated that some years ago he attended a patient in her eleventh pregnancy. She had loss of sight, convulsions, milk leg. In the twelfth pregnancy there was no albuminuria whatever. In the former instance Dr. Wadsworth examined the eyes the day after the labor, with negative result.

A MEMBER reported Dr. Wadsworth as saying that it was possible for marked loss of sight to occur without ophthalmoscopic evidence of the cause.

DR. LYMAN said that he had supposed changes in the retina were always found in impaired vision due to Bright's disease. If that were the case the ophthalmoscope should show something twenty-four hours after the symptom.

DR. MIXOT remarked that he doubted very much whether any change noticeable by the ophthalmoscope would be found in those instances of transient blindness due to the acute disease.

A CASE OF LABOR WITH ABNORMAL PRESENTATION; DECAPITATION.

DR. FIFIELD reported the case, stating that about a month ago he was called to assist in a case of difficult labor, in which the physician in attendance had been unable to effect delivery. The patient, a Scotch woman, had had two previous labors: the first natural, the second effected by forceps. In the present instance

she had been (as Dr. Fifeild understood) taken in labor at some time on a Thursday, but it was not until the afternoon or evening of the following day that the attendant had been able to make out the presentation, which was diagnosed as that of the breech, very high up. The forceps were then applied, and an arm had come down. An attempt was next made to turn, but unsuccessfully. A consultant was called, and a second trial of version made without avail. Nothing short of decapitation seemed able to deliver the woman.

When Dr. Fifeild was called the left arm was hanging from the vulva, livid, cold, and dead. Tracing this, he found, high up, the sterno-clavicular region. The head was thrown into the left portion of the pelvic basin. The lower extremities were out of reach, and decapitation seemed to Dr. Fifeild to be the only possible resource. This was accomplished by dividing the bones of the spine with a pair of Smellie's scissors, the muscles to a very small extent with long scissors, and then tearing through the neck with a blunt hook (the only instrument at hand), the body was almost immediately born. The head was then pressed down into the pelvic canal, and was finally delivered thence by a crotchet introduced into the mouth. In using the scissors great care was necessary in guarding its sharp points from the uterine tissue. The patient made a good recovery. Dr. Fifeild remarked that he had been long familiar with the midwifery of Plymouth and Norfolk counties, both in his own and in the sixty years' practice of his father, covering a period of eighty-five years and more, and yet he had never heard or known of a decapitation being performed in the region mentioned. In answer to questions, Dr. Fifeild stated that he did not turn because he could not reach a lower extremity; moreover, the waters had been evacuated some hours before his arrival.

Dr. MIXOT suggested that a very strong pair of curved scissors, such as are used for dividing the neck of a polypus, might be employed in decapitation.

Dr. FIFEILD said that with the long, sharp pointed scissors it was difficult to avoid injuring the womb, and really they were of slight service in the case. Regarding the manner of using the hook recently described and advocated by Dr. Richardson, it did not seem to commend itself, inasmuch as a twist sufficient to break the neck might bring the face against the uterine surface with damaging force. Dr. Fifeild observed that decapitation is said to have been done by passing a string around the neck, and then using it after the manner of a chain-saw with the two hands.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

A NEW METHOD OF PERFORMING OVARIOTOMY.

At a meeting of the New York County Medical Society held January 24, 1880, Dr. Emil Noeggerath read a paper on the above subject. The results of operations for the removal of ovarian tumors, he said, had become so very satisfactory with our great gynecological surgeons, that with many of them success was the rule, failure to save the patient's life the exception; but since we must attempt to reach even better results, and lessen the number of deaths following difficult and protracted operations, any step directed toward the dangers connected with laparotomy

should be considered in order. The question of the importance of antiseptics during the performance of ovariectomy was, to some extent, still a mooted one; but from what he had seen in his own practice and in that of others, he had come to the conclusion that the more extensively antiseptics was applied, and the more varied was its use in a single case, the greater were the chances of recovery.

If we should not succeed in gradually working out a plan by which patients might be operated upon easily at their own homes, or in the hospitals spread over the country, we ought to send every case of ovariectomy to one or more central points, where all the circumstances were made so to cooperate that the life of the patient was rendered as safe as it could possibly be rendered. One great advantage of these centres of science and wealth was the institution of isolating wards or cottages designed exclusively to receive patients during and after the operation. The question arose, then, whether it was possible to make a room in a dwelling or a private room in a hospital as salubrious as one of these cottages at an establishment like the New York State Woman's Hospital. Dr. Noeggerath believed that he could answer in the affirmative, at least as regards the time during the operation and the next few days afterward; and he described his method of procedure as follows: "If I can have them, I select two rooms — if not, one — on the first floor; and begin with the removal of the carpets, all of the furniture, pictures, looking-glasses, bureaus, etc. Now the floor, walls, and ceiling are washed, first with water and then with a two-and-a-half per cent. solution of carbolic acid, on the day preceding the operation; after which vessels containing chlorine water are placed in the rooms and in front of the doors. The wash-closet, if any be present, is hermetically sealed up; all the water to be used afterward to be carried in from without. The mattresses have meanwhile been aired, and the bed-clothes, the suit or suits which are worn during and after the operation, and the towels have been washed in carbolic acid solution. On the evening preceding the operation all of the last-named articles, with two wooden tables, a chair, and an iron bedstead, or stretcher, are placed in the room. The windows are closed, and a piece of sulphur is burned for about half an hour. The outer dress of the nurse is also disinfected. After the operation the room is heated by a grate-fire, and a kettle containing carbolic acid solution is suspended so near the fire as to produce enough evaporation to have its presence remarked when you pass into the room. The nurse enters and leaves only through the adjoining chamber, which is exposed to the air day and night. Thus, conditions are presented which closely resemble those of an isolated cottage."

Having spoken of the three principal sources of danger, — hemorrhage, shock, and septicæmia, — each alone, or two or more combined, constituting the most frequent cause of death, the writer considered the question how to avoid shock. From Wegener's experiments on animals, and from clinical observations, which had been made since then, it could be assumed that the principal element of shock was lowering of temperature. Since so large a surface was exposed to evaporation, it could readily be seen how this cause would operate in ovariectomy. Another element in the production of shock was the prolonged contact of the contents of the abdomen with fingers, instruments,

etc., and their unavoidable dislocation; a fact also proven by experiments on animals. If we added to these the influence of narcotism, with its paralyzing effect on the heart, its well-known tendency to lower the temperature of the body, and the injurious effect of vomiting, which added to the mechanical insult offered to the viscera, he thought he had enumerated all the circumstances, a combination of which rendered laparotomy dangerous from this source. Beginning with the last, he then gave an account of the manner in which he attempted to prevent shock. After a long trial with the usual anæsthetics, he had returned to the use of chloroform, first, because he had failed in a number of instances to produce deep and uninterrupted sleep with ether; and, secondly, because nausea, vomiting, and coughing during and after the operation had been less frequent after the use of chloroform. A patient to be operated upon in the afternoon of a certain day was ordered to take on the day previous, and the one preceding this, one drachm, and on the morning before the operation thirty grains, of bromide of potassium, in accordance with the plan formerly proposed by Dr. Lente. The patients required less of the anæsthetic; the period of excitement was considerably diminished; the sleep was more natural; and vomiting was less frequent than without it. For the last two years he had added another safeguard also; namely, the administration of one or more doses of thirty grains of chloral per rectum; and since he had been employing bromide of potassium before, and chloral after, ovariectomy, vomiting had been an extremely rare occurrence. In order to prevent lowering of the temperature, he placed his patients on a rubber bed filled with water heated to 100° F. or 110° F. Dry heat was much less depressing than damp heat, which was almost universally employed, because it did not interfere with the evaporation from the lungs and from the skin; and it possessed the further advantage that it could be conveyed to the body in just such unvariable strength and duration as was required. Still another advantage over the old method was its effect upon the reflex centres in the spinal cord. Abdominal hyperæmia had been proved to be an essential element and a direct consequence of shock, and if we included with the reflex paralysis of the vaso-motor system that of the splanchnicus, in consequence of traumatic insult, all the phenomena were explained: the patients were pale; the brain was anæmic; the heart contained little blood, and the portal system of veins were engorged. We could, therefore, measure to a certain extent the degree of shock which was developed during ovariectomy by the amount of hyperæmia found inside the abdominal cavity; but since he had operated with his patients on the hot-water bed he had observed that even in operations where the viscera had been exposed more than an hour and a half the abdominal blood-supply had not apparently been larger than in the normal state.

The most important danger connected with ovariectomy, he continued, consisted in the formation of septic material in the abdominal cavity after the operation; and it was evident that it must be the effort of the surgeon to allow as little septic matter as possible to come in contact with the serous membrane. The desired object would be obtained most effectively if we could lessen the space and time of contact of the peritonæum with the air, hands, and instruments from what was now the case in the method of operating or-

dinarily employed. Dr. Noeggerath then gave the following details of the plan which he had adopted: "I commence by incising the skin, the subcutaneous layer of fat, and the fascia superficialis to the extent of about three inches. Instead of going on incising the tissues down to and through the peritonæum, I plunge the trocar at once into the cyst and empty it out. If I find that the liquid is bland, I proceed with the operation; if it should contain pus, decomposed blood, or dark, grumous fluid, I inject through the tube attached to the trocar about half as much of a two-and-a-half per cent. solution of carbolic acid as the fluid measured when removed. This is allowed to remain in the cyst for a while and is then withdrawn. This is done in order to remove the possibility of infecting matter passing from the cyst into the abdominal cavity during the further progress of the operation. After the cyst is fully emptied I depress the handle of the trocar toward the skin below the umbilicus, thus carrying all that section of the tumor which lies below the opening of the trocar against the anterior abdominal wall. Now the uplifted portion of the latter is incised upon the trocar, as a guide, down to the cyst-wall, which is lifted up and out of the peritoneal cavity by the instrument inside it, after which the pedicle is tied and the cyst removed." The advantages claimed for this proceeding over the ordinary method are the following: (1.) It simplifies the operation considerably, since the search for, and separate opening of, the serous membrane are entirely done away, thus removing the principal difficulty connected with that part of the operation which precedes the opening of the cyst itself. (2.) The chances of air, instruments, and hands, contaminated with septic material, entering the abdomen are considerably diminished, partly because the time during which the peritoneal cavity is exposed to their contact is shortened by just so much as it takes to empty out the sac; partly because the cyst collapses before the cavity is opened, and the suction originating from the inequable contraction of the sac and the abdominal walls is entirely done away with. (3.) The chance of noxious contents of the tumor running into the abdominal cavity is very much less as compared with the ordinary proceeding, and they can be rendered harmless by previous disinfection. (4.) The opening in the peritonæum is, on an average, smaller than with the old method, it being adapted in every single instance exactly to the requirements of the case. (5.) The shock which results from laying open the abdominal cavity is shortened by just so much time as it takes to empty out the cyst, the greater part of the operation being reduced to that of simple tapping.

The only two contra-indications to this method of which Dr. Noeggerath knew were: (1.) A preponderance of the solid over the liquid portion of the tumor, or where the whole mass consisted of very small cysts or semi-solid contents, too thick to pass through the canula. (2.) A small sac, either originally so, or reduced by previous tapping, on account of the danger of encountering a loop of intestine in front of the cyst. A third possible contra-indication would be the presence of ascites, but he had had no occasion to test this question practically. If anything unusual should occur after commencing with his proceeding, however, it could be interrupted at any step, and the operation finished after the ordinary method. At first sight the presence of adhesions might be taken for a grave objection, but during the operations performed

after his method he had met with the ordinary run of adhesive inflammation, its products extending to the omentum, the lateral parietes and anterior surface, and spreading far into the pelvis; yet he had found no difficulty in separating them, one after another, from the collapsed sac.

Of the twelve patients upon whom the operation had been performed, three had died and nine recovered. Numerically, this was a small percentage, but of the three patients who died one was forty-five, one seventy-one, and one seventy-five years old. The two latter had evidently atheromatous degeneration of the arteries. In the case of the first of these patients only four fifths of the cyst could be removed, on account of adhesions to the spinal column and the true pelvis. The ligature applied to the remaining mass, which he intended to treat according to the plan of Dr. Atlee, was tied in what is known as the Staffordshire knot. It slipped, and before another one could be applied a fearful hemorrhage occurred, which the woman only survived for three hours.

Before proceeding to describe his new method of after-treatment, the writer stated that in ordinary cases he left his patients for the week following the operation on the water-bed, which he now filled with cold water as soon as a rise of temperature called for antipyretic measures. He had found it as efficient as Kibbee's cot, and it had the great advantage over the latter of putting less strain on the nurse and causing less disturbance of the patient. If symptoms of nervous depression, or even collapse, were to begin to develop it could be filled again with hot water, and its stimulating effects thus called into action. The after-treatment properly began at the time when the cyst was being severed from its pedicle,—that is to say, we had at this moment to decide whether the peritoneal wound, namely, the peritoneal cavity, was to be treated as an open wound or to be closed. Although it was generally admitted that the question regarding the treatment of the pedicle was so far settled that in the large majority of instances the intra-peritoneal method was the one to be chosen, there remained a certain percentage in which drainage which was the only proper treatment. He then expressed the conviction that drainage of the pelvic cavity, as practiced by surgeons at the present day, no matter of what shape or material the tube was made, was a source of danger.

The only reasonable method of drainage was that proposed and performed with great success by Dr. Barskneuer, of Cologne, who had returned to the original idea of Sims, and drained the abdominal cavity through Douglas's cul-de-sac, with such modifications, however, as to overcome its disadvantages and dangers, on account of which it had been generally abandoned. He incised the cul-de-sac to the extent of at least an inch and a half, and introduced a tube of the size of the finger, with a number of large orifices in the supra-vaginal portion of it. To the tube there was further attached a cross piece, also perforated, for the drainage of the base of the pelvis. But even if we had an absolutely reliable method for draining Douglas's cul-de-sac, cases undoubtedly occurred where the procedure would fail; and Dr. Noeggerath had, therefore, employed a new method of after-treatment for cases where drainage was indicated. It consisted in the use of the permanent, full bath, the water being allowed to remain in constant contact with the peritoneal cavity. The bath used for treating patients after

ovariotomy consisted of a large tank made of boiler-iron, joined and riveted like a steam boiler, having beneath it a chamber, of about two inches in depth, for the reception of steam, in order to maintain the temperature of the water at an equal rate without such frequent changing as would otherwise be necessary. All along and outside its upper border were projecting iron pegs for the purpose of attaching a hammock, on which the patient lay in the water. The bath was connected with the hot and cold water-pipes, and also with the steam-pipes, and the hot and cold water was made to mingle in one common pipe before entering the tub, so that it could neither chill nor scald the patient as it ran in. Although it was desirable to have a bath as complete as the one described, it could be very well substituted in a private dwelling by a common movable bath-tub with a double bottom for the reception of hot water. The explanation of the action of the perpetual contact of water in preventing sepsis consisted in the fact, established by Wernich, that water in abundance is one of the most reliable agents for destroying bacteria. To the water was added enough common salt to make not quite a one half per cent. solution, and a small quantity of salicylic acid. The number of cases he had treated with the bath was too small to shape any final indications for its use. He knew, however, already one contra-indication, and within its scope are comprised patients with weakened constitutions. The drain on the system from loss of serum and fibrine was severe. Dr. Noeggerath said, in conclusion, that he proposed to employ the permanent bath as a substitute for ordinary drainage in ovariotomy, and, above all, after Freund's operation, after the removal of fibroid tumors, and after Caesarean section. He further stated that in the bath in one case an abdominal fistula an inch and a half in length, from which all of the solid faecal matter had been discharged for weeks, was closed in four days and a half so thoroughly that no feces were afterwards discharged through it.

In the discussion which followed the reading of the paper the following points were taken up by Dr. Emmet and other speakers:—

Is anti-sepsis altogether necessary?

Is the spray alone sufficient?

Is it safe to exclude the spray from the anti-septic method?

Is anti-sepsis feasible in private dwellings and in ordinary hospitals, as well as in the isolated cottages used only for ovariotomy cases?

Is chloroform or ether preferable as an anæsthetic?

What are the best methods of avoiding shock?

What are the disadvantages and contra-indications against puncturing the cyst before opening the peritoneal cavity?

Is the intra-peritoneal method of treating the pedicle applicable to all cases?

The advantages and disadvantages of drainage.

Quinine *versus* cold water in the after-treatment.

Drs. Thomas and Bozeman were expected to speak upon the paper, but were unfortunately both prevented from being present by illness.

—An interesting account of the examination of thermometers at the Yale Observatory, particularly of the establishment of the standards, by Mr. Waldo, astronomer in charge, may be found in the *Popular Science Monthly* for January.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 10, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

SMALL-POX AND REVACCINATION

OUR readers are doubtless aware by this time of the many indications that another outbreak of small-pox may be at hand. The last epidemic subsided early in 1874, after a duration of two years, in the course of which the disease proved fatal to 1040 persons in Boston. Since then we have enjoyed an unusually long period of immunity, extending over seven years. The disease is now, however, awaking from its long slumber, and, like a giant refreshed, is ready to renew its onslaught. From Europe, where it has prevailed during the past year, it has reached this country, and has established a foothold in several of our great cities of the Atlantic coast. In New York during the week ending January 8th, there were 20 deaths from small-pox; in the week ending January 15th, there were 10 deaths; and in the week ending January 22d, again 20. In Philadelphia the weekly deaths by small-pox have lately exceeded 50. In Boston, however, no deaths from this disease have as yet been reported.

Such being the present situation, what now is the outlook? In the absence of any prophetic gift, we must be content to read the future from the past. Let us, therefore, first consider the history of small-pox in Boston, as exhibited in our records of registration.

The following table shows the yearly deaths by small-pox, in Boston, since the year 1811:—

Years.	Deaths.	Years.	Deaths.	Years.	Deaths.
1811	2	1833	—	1855	132
1812	—	1834	4	1856	78
1813	—	1835	7	1857	2
1814	—	1836	6	1858	3
1815	4	1837	13	1859	156
1816	—	1838	3	1860	162
1817	—	1839	60	1861	7
1818	—	1840	115	1862	13
1819	—	1841	57	1863	11
1820	—	1842	42	1864	113
1821	—	1843	55	1865	115
1822	—	1844	—	1866	51
1823	—	1845	31	1867	144
1824	1	1846	92	1868	8
1825	1	1847	23	1869	6
1826	—	1848	21	1870	32
1827	3	1849	21	1871	28
1828	2	1850	192	1872	738
1829	—	1851	63	1873	302
1830	—	1852	12	1874	2
1831	4	1853	6		
1832	2	1854	118		

introduction of vaccination in 1800, gradually regained its foothold in Boston, where it continued to prevail almost uninterruptedly, although with varying intensity, from 1839, when the disease for the first time assumed the form of a distinct epidemic, up to 1873. During this period of thirty-five years the course of small-pox has been marked by a succession of epidemic paroxysms, generally lasting from one to two years and separated by intervals of several years, during which a varying number of sporadic cases has testified to the more or less constant presence of the disease.

The latest epidemic, that of 1872-1873, having proved fatal to 1040 persons, was the most severe that has been experienced in Boston since the introduction of vaccination. In 1872 the death-rate by small-pox was 2.78 per 1000 living persons, and the deaths so caused amounting to 9.11 per cent. of the deaths by all causes. In 1873 the death-rate was 1.57, the percentage being 5.54.

Taking now the ages of decedents by small-pox, we can determine the ages at which the protection afforded by vaccination, as hitherto carried out in Boston, has proved insufficient. The following table contains two columns: the one showing the percentages of decedents at selected ages, in 1872; the other showing the percentages of inhabitants living at the same ages to the aggregate population:—

Ages.	Percentage on all Deaths by Small-pox, 1872.	Percentage on Aggregate Population.
Under 5 years . . .	26.5	12.5
5 to 15	5.8	18.5
15 to 20	11.3	9.6
20 to 30	36.0	24.6
30 to 40	12.4	16.8
Over 40	7.9	17.9

We here see that children until five, although constituting only 12.5 per cent. of the population, contributed 26.5 per cent. of all deaths by small-pox; while youths between 5 and 15, making 18.5 per cent. of the living, contributed only 5.8 per cent. of the decedents. The contrast between these two sets of figures is very striking, and shows, in the most peremptory manner, the deficiency of protection in the first years of life, and the efficacy of vaccination practiced later on, at the ages of school attendance. The relative degree of exemption enjoyed during adolescence and resulting from the postponed vaccination, undergone in obedience to the requirements of school-attendance, is seen to disappear gradually, so that we find again, between the ages of 20 and 30, a marked liability to fatal small-pox, which can bear but one interpretation: we here see evidence of an insufficient practice of *revaccination*, which measure of prevention is shown to become necessary within a space of 8, 10, or 12 years after the first vaccination usually undergone in childhood. Later in life, at ages from 30 to 40, and upwards, the liability to small-pox is known to diminish considerably, independently of preventive measures; and figures show this to have been the case in Boston.

From these figures we learn that small-pox, after having almost wholly disappeared from our community during the thirty or forty years which followed the

Such having been our past experience of this justly dreaded disease, which maims or disfigures so many more victims than it kills, what is the lesson to be learned and acted upon? The inference from all that we have heretofore suffered, and, indeed, from all the acquired knowledge and wisdom of civilized mankind, is obviously to the effect that every available means of prevention that is known to hygiene, whether public or private, should be got ready and brought to bear without delay, in order to forestall and ward off the first onslaught of the impending epidemic upon our community. The means of prophylaxis are familiar to all: vaccination, which annuls or greatly lessens the susceptibility to small-pox, is acknowledged to be the most powerful agency of prevention at our disposal; isolation of the sick, which prevents or restricts the dissemination of the contagium, is an efficient means of checking the spread of the disease. These two agencies are put into the hands of our sanitary authorities as weapons, to be used, if necessary, with compulsion.

Vaccination, however, as administered by our boards of health, as a compulsory measure, is legally limited in its application to the ages below the period of school attendance. In this form it reaches only infants and young children. At later ages, our sanitary authorities cease to exercise any supervision or intervention in this matter, and revaccination, a measure universally recognized as necessary after intervals of eight or ten years from the most recent successful vaccination, is a purely voluntary means of prevention, which all grown-up persons are free to adopt, but which they are also at liberty to postpone or altogether neglect.

Experience has shown that, in this community, the benefits of revaccination are far from sufficiently appreciated and utilized by the public. Such ignorance and inertness having been distinctly shown to be in the highest degree prejudicial, it is manifestly the duty of all physicians to do their utmost to counteract these shortcomings, by instructing and stimulating all those with whom they are thrown in contact, and by arousing in them a proper sense of their duty in this serious matter.

This is not the only community where the necessity of attention to revaccination has to be emphasized. In a recent editorial of the London *Lancet*¹ it was asserted that "since the great epidemic of small-pox in 1871-72 revaccination has assumed an importance in the question of vaccination it had not before possessed, particularly on account of the great number of persons who have been seized with small-pox beyond the age to which the compulsory clauses of the vaccination acts apply. It is to this class of persons that the present condition of things in the metropolis has peculiar importance. Their safety rests wholly with themselves, and assuming that they have all been vaccinated in infancy, an effective revaccination will make them more certainly proof against the disease than if they had previously suffered from it. . . . But one thing is clear, that persons who ought to be

revaccinated will act unwisely if they are not revaccinated as early as practicable, not waiting until the full swing of the epidemic (if it is to come) be upon us, when an abundant experience has taught us that it is not always easy to secure an efficient revaccination, partly from a deficient lymph supply, and partly from the condition of performance of the operation not always being the best."

Let our motto be *principiis obsta*; the means of resistance, vaccination, isolation, and revaccination; the two first agencies to be applied, if necessary as compulsory measures, by our sanitary authorities; the third, revaccination, needing to be strenuously urged upon the public, and carried out by the medical profession.

SINGLE AND DOUBLE SCHOOL SESSIONS ONCE MORE.

OUR esteemed correspondent, Ingleby, has favored the JOURNAL with another communication, to be found in another column, on the subject of school hours. In connection with the Prince School he gives the results of careful inquiries as to the ages of the pupils, which are interesting, as showing at what a tender age many children are sent to public schools, even in such a district as that where the Prince School is situated. We were evidently in error in believing from inquiries, made in a general way, that the majority of the children at that school are between twelve and sixteen years of age. We can only say we are sorry they are not, but see no occasion to change our opinions or the expression of them, which we strove to make plain and concise, in any way.

The original question at issue was one of single or double school sessions, the question of hours was a somewhat secondary one, brought, however, into more prominence by Ingleby's dislike to the reference made to Chadwick's deductions.

Whatever the proper number of hours of study may be for small children that number should be adopted for them, but we do not think it would be for their advantage to have a morning and afternoon school session through the winter in the new part of this city. Nor do we see why older children should be rescued from a five hours' session because younger ones ought not to remain at school more than three or four.

MEDICAL NOTES.

— The following is the proposed list of subjects for discussion in the Section of Medicine, at the International Medical Congress next August: (1.) Localization of disease in brain and spinal cord, so far as pathognomonic and diagnostic. (2.) Trophic changes of nerve origin. (3.) Vascular changes, functional and organic, in disease. (4.) Primary disease of the lymph system. (5.) Gout, rheumatoid arthritis, and rheumatism. (6.) Forms of renal diseases (Bright's diseases). (7.) Methods of physical diagnosis. (8.) Therapeutic methods: revulsions, blood-letting, diet-cure, uses of heat and cold, drug-cure, etc.

¹ The Lancet, January 15, 1881, page 106.

—An editorial in the *Philadelphia Medical Times* for January 29th, which is ascribed to the pen of Dr. Hamilton Osgood, under the title of the Amenities of Medical Journalism, gives prominence to the dark side of the editor's occupation.

—Dr. Daniel Perley, of Lynn, died on January 31st, after three years' illness, at the age of seventy-seven. He was born in Boxford, Mass. Received from Dartmouth the degree of A. B. in 1828, and of M. D. in 1831. Since 1831 he has practiced his profession in Lynn, and when obliged by sickness to retire from active life was the oldest practitioner in the city.

—In the *Comptes Rendus*, xci., Professor Bouchut speaks of some experiments he has made going to show that the milky juice of the fig-tree possesses a fermentative power of a digestive character. Having mixed some of it with a preparation from animal tissue, he found the latter well preserved at the end of a month. This fact, when brought into connection with Professor Billroth's case of cancer of the breast, which was so excessively foul smelling that all his deodorizers failed, but which, on applying a poultice made of dried figs cooked in milk, lost entirely the previously unbearable odor, gives an importance to this homely remedy not to be denied. — *Medical Press and Circular*.

—Professor Laboulbène, in a long and interesting lecture on the history of medical journalism, gives the following list of the leading medical periodicals published in America: *The American Journal*, *Boston Medical and Surgical Journal*, the reviews and medical journals of Cincinnati, Indiana (!), New York, etc., etc. — *Philadelphia Medical Times*.

—The Paris correspondent of the *Lancet* describes the plan of an ingenious philanthropist to diminish the mortality amongst the wounded in war by tattooing on the soldiers' bodies the principal points where compression may be made in cases of hemorrhage. Life may be lost in a few minutes by a wound of a large artery, and it is thought that the soldier might often escape if he knew where to command an artery whilst waiting for help.

WASHINGTON.

—On Wednesday, January 20th, Senator Williams, of Kentucky, called up, in the United States senate, the bill previously introduced by him to prevent the introduction and dissemination of epizootics or communicable diseases of domestic animals in the United States, upon which he made some extensive and valuable practical remarks. The bill was at his request referred to a select committee of five. The purport of the bill is to make it unlawful to import or introduce into or from one section to another of the United States any animal affected with a communicable, infectious, or contagious disease, except in accordance with provisions as set forth in the bill, or to offer for sale or sell the same, detailing especially such diseases as contagious pleuro-pneumonia, splenic fever, foot and mouth disease, hog-cholera, trichinosis, farcy, and glanders, etc. In its various sections the bill

gives the National Board of Health full power to report infected localities, directs United States district attorneys to prosecute violations, imposes fines from one hundred dollars to five thousand dollars, and imprisonment for not more than a year for such violations, authorizes investigations, and reports on the part of the National Board of Health, both in this country and abroad, with power to draught the necessary rules and regulations, to appoint a duly qualified veterinary supervisor, who shall be *ex officio* member of said board, to appoint veterinary surgeons, a sufficient clerical force, inspectors in foreign ports, etc., for the necessary carrying out of the provisions of the bill. The president is authorized to detail officers for this purpose, and one million dollars is the sum named to be appropriated to meet expenses incurred.

Senator Williams gave a comprehensive review of the prevalence abroad of cattle disease and its introduction into this country; he referred to Professor Gamgee's report of 1862 as first proving pleuro-pneumonia to be exotic and not indigenous, as had been supposed up to that time. The English restrictions upon the importation of cattle were made to protect their native herds from new infection from abroad while they were stamping it out at home, and the English are as anxious to get our cattle as we to sell them. He quotes Mr. T. C. Anderson, a short-horn breeder, as saying that within the last year we have shipped to England one hundred and fifty thousand high grade fat steers, worth one hundred dollars each, and that these would have brought one hundred and forty dollars more per head could they have been put out to grass to recover from the effects of the voyage. Since the Brooklyn importation of the Dutch cow a contagious distemper has spread almost unchecked. Massachusetts stamped it out completely as far back as 1867. No case of lung plague has occurred west of the Alleghanies, but within the last year forty thousand calves have been shipped from the Eastern States to the cattle yards of Chicago, so that it is but a question of time as to when we shall have a repetition of the experience of Great Britain, where these calves, infected in pestilential cow-sheds, carried disease wherever they went. Within the space of forty years Great Britain, with six millions of cattle, has lost by death alone from this plague more than five hundred millions of dollars. Pleuro-pneumonia usually kills from forty to seventy per cent. Such animals as appear to have recovered are so enfeebled as to be worthless for work, breeding, or beef. Another threatening source of danger is the importation of short-horn, Hereford, Holstein, and Alderney cows from Europe. Their aristocratic respectability gives them an easy passport, yet some of the largest and most valuable herds of England have been destroyed by this plague. The number of live stock in our country is estimated at forty-five millions of cattle, eighteen millions of mules and horses, fifty millions of sheep, and sixty millions of swine, worth in the aggregate three billions of dollars.

A necessary proviso in the bill is that affording compensation to the owners for the slaughter of in-

fect or sick animals, otherwise they will hide them in out-of-the-way places, or run them off and sell them to innocent purchasers, and thus establish new centres of infection.

Recent Literature.

Ophthalmic and Otic Contributions. By D. B. ST. JOHN ROOSA, M. D. and EDWARD T. ELY, M. D. New York: G. P. Putnam's Sons. 8vo, pages 107.

This book consists entirely of reprints of papers by the authors which have already appeared in various journals. They are nearly equally divided between the two subjects, and in the form here presented are convenient for the library and for reference.

The Pathology, Diagnosis, and Treatment of Diseases of Women, including the Diagnosis of Pregnancy. By G. HEWITT, M. D. Third American from third London edition. Philadelphia: Lindsay & Blakiston. 1880.

In the present edition the author argues strongly in favor of the mechanical theory of uterine pathology; and many of his statements are forcible, full of sound reasoning, and borne out by daily clinical experience. Far too commonly, however, he ascribes the sufferings of the patient, primarily, to deviations in the position of the uterus. The position delineated in Figure 10, as the normal one, is too much inclined towards retroversion and retrocession, and is not that supported by most American authorities, nor the one commended to use by personal experience.

Chapter V., on the Diagnosis of Pregnancy, considering as it does the several conditions so often confounded with it, is exceedingly good, and full of sound and practical points. If practitioners would follow the instructions here given, they would, we are sure, make fewer mistakes in the diagnosis of pregnancy, and oftentimes spare themselves discredit and ridicule.

The very best part of the book is that on Flexions, or acquired deformities of the uterus, more especially that portion of the subject which treats of the causes of these malpositions. The author seems to have been particularly interested in this whole matter, and treats it in a manner correspondingly pleasing and satisfactory. He especially enforces the effect of antelexion in producing abortions, claiming a greater tendency to this accident than in retroflexion, and drawing his conclusions from two hundred and thirty-five cases of married women suffering from ante or retroflexion, treated in the University College Hospital, sixty-eight of whom had aborted one or more times. The treatment recommended for these flexions seems rather faulty, both as regards methods of replacement and means of retaining the organ in position; for example, the sound is too generally used for replacement, and the forms of appliances (particularly for backward displacements) ineffectual, certainly in the large majority of cases which it falls to our lot to treat.

Among typographical errors, mostly of small account, we notice on page 273, the word *perineum* used for *perineum*, in a sense which might well confound and lead to error.

The descriptions of the different gynecological oper-

ations, particularly that for rupture of the perineum, are quite imperfect and unsatisfactory. In fact, the whole subject of operative gynecology falls below the general high standard of the book.

It is a mistake to devote chapters to such symptoms of disease as amenorrhœa, menorrhagia, and dysmenorrhœa. They seem to us more properly considered under the head of the diseased condition which give rise to them.

Miscellany.

FIVE HOURS OF STUDY, ONCE MORE.

MR. EDITOR, — After a silence of four weeks, it is, perhaps, hardly courteous to recur again to the question of the long session at the Prince School. But on inquiry, the facts in the case have been found to be so exactly contrary to those on which the criticisms of the JOURNAL were based, that we now hope in presenting them to obtain an entire reversal of its judgment.

We quote from the editorial in the issue of December 30, 1880, page 645: "Our remarks were limited to children between the ages of twelve and sixteen, because we believed the majority of the children concerned to be between those ages, and should be sorry to think that this was not the case; moreover, in our estimation it is only for children between these ages that the question of a single or double session should come up at all."

The statistics appended, which are printed by authority, will, we think, prove that we have not without reason striven to attract the attention of the JOURNAL and its readers to this very great wrong done to little children. We have great pleasure in believing that they will show that the JOURNAL is "in hearty accord" with us in its judgment upon the real question at issue. To those who knew the influences at work in the Prince district, the result of the controversy was a foregone conclusion. But a deep conviction of the evil inflicted compelled us to make all the effort in our power to direct public attention to the subject. We had, we admit, counted upon the warmest approval of our views from the medical profession and from the JOURNAL. It was a bitter disappointment not to receive this indorsement. And it is with unqualified satisfaction that we now see that the disagreement was only apparent; that the words above quoted, when coupled with the statement which is here annexed, authorize us to expect the hearty support of the JOURNAL in the position which we have taken.

The children in the Prince building number four hundred and forty.

Of these, two hundred and ninety-nine (all but *three hundred*) are less than twelve years old.

Of these latter, *one hundred and thirty* are not nine years of age.

While the whole number *over twelve* is only one hundred and forty-one.

Nor is this all. Of the children *under nine years*, fifty-six are kept at school *five hours*; and the eighty-four others for *four hours and a quarter*.

In view of these facts, now for the first time made plain to the JOURNAL, may we not ask, in accordance with its own opinions above quoted, an acknowledgment that there is no want of accord between it and

us, and claim its earnest support in our protest against a procedure which violates equally the laws of school hygiene and the dictates of common sense?

CHAS. INGLERY.

THE GERMAN PRIVAT-DOCENT.

MR. EDITOR. — It has been my intention for some time, but one thing or another has prevented, to express to you my gratification on reading the educational number (October 14, 1880) of the Boston Medical and Surgical Journal. I take this first opportunity to do so, and at the same time the liberty of correcting, through your Philadelphia correspondent, a point in relation to that part of the article on foreign schools, which gives the impression to the reader that any graduate of medicine can set up lecturing as *privat-docent* at any time and place in Germany with the same freedom as in this country.

Having had an experience of several years as a medical student in the universities at Munich, Berlin, and Jena, I can assure you that it is not so easy a task to become a *privat-docent*. As it is the first step towards a professorship, they are as rigid and particular with it as with anything else in relation to education in that country.

I know that in my time to lecture upon any subject it was necessary, first, to be a graduate of at least two or three years' standing; second, to write for the faculty an original and exhaustive dissertation on the branch that the person desired to lecture on. If approved, a public examination was given upon the subject by the professor connected with the university in which the candidate is required publicly to defend his ideas and propositions. If this examination is creditable, a certificate creating him a *privat-docent*, with the permission to lecture, is given him by the faculty, approved by the provost of the university, and in some cases countersigned by the minister of public instruction.

To become a professor in Germany one must give evidence of not only learning but originality of thought and work on the subject he professes to teach. This is learned by the method of teaching in that country, as well as the system of rearing teachers through the school and promotion of lecturer (*privat-docent*) (where discoveries and original ideas generate) to that of extraordinary (*ausserordentlicher*) professor, and then to the full professorship (*ordentlicher professor*).

Original thinkers and workers as *privat-docent* soon become men of mark, and known all over the country. They become candidates for vacant chairs in any of the universities, and are called to fill such positions without regard to the locality of the school from which they are graduates. By this method education becomes, as it should be, cosmopolitan, and not local or sectarian. In this way only men of real ability reach such places, and become the teachers of the students. What a glorious day it will be for our great country when this system of filling all the chairs in our schools, colleges, and universities by independent, original thinkers and brain workers, without regard to their *alma mater*, shall be adopted instead of the present method of personal, social, political, and other degrading influences. I have the honor to be yours very truly,

P. D. KEYSER, M. D.

PHILADELPHIA, January 24, 1881.

In our account of the German *privat-docent* it was said that this position was *accessible* to any one having the degree of doctor of medicine. The use of this word, though scarcely erroneous, may very possibly have proved misleading. We are always glad to notice any corrections of statements in the educational number, the object being to perfect it as far as possible in the future. The continued evidences of the interest excited by that number of the JOURNAL are gratifying. — Ed.

ANTISEPTIC SPRAY.

MR. EDITOR. — It is to be regretted that in bringing before your readers the subject of the spray in surgery, in your issue of January 20th, the editor did not take pains to inform himself more fully in the matter. Bruns' article with a sensational title was quoted, and Mikulicz's experiments, which need further examination before acceptance as authoritative; but Dr. A. T. Cabot's excellent observations, and Dr. Watson's in reply to the original article by Dr. Stimson a year ago, are not referred to. Probably the editors only read German medical literature, or are desirous of avoiding "provincialism," the bugbear Mr. Henry James attempts to frighten us with, and dread quoting their countrymen. At any rate they looked for their science to the land of Schreib-Tisch generalization, and neglected the home productions, in this case of much better quality.

The writer does not even seem to have considered the arguments of those whom he quotes as authority, but mentions Dr. Homans's twenty-five cases as illustrating the fact that the spray is useful in ovariectomy. If Bruns and Mikulicz are correct in their reasoning the spray is not a means for covering the wound with a purified atmosphere, but is a poor method of irrigation.

If this view is true, spray in ovariectomy is certainly of little use; for it is inefficient in irrigating or washing the cavity of the abdomen, to which the air (but little purified according to these authorities) has complete access. If, however, the spray is beneficial not simply as a wash, but as conveying an antiseptic atmosphere, is a surgeon justified in any large operation laying open to the air an amount of tissue of any extent, by contenting himself with an occasional wash?

The fact of the matter is that very little as yet is known as to the action of the spray; and for the present the conservative surgeon does not expose his patients to possible risks, because he is inconvenienced. We venture to say that if ten of the skeptics as to the spray were obliged to submit to the operation of incising the knee-joint and wiring a fractured patella, at least nine of them would prefer that the spray be used. It might be unnecessary; but it might not. The tenth would probably regard his chance as at best a small one.

A superficial article on this subject is more to be regretted, as in this community there is a greater danger of half doing antiseptic surgery than of overdoing it.

In the wards of our hospitals perfectly antiseptic dressings are not very common, and what is needed is more thoroughness and not the spirit of the doubting Thomas, who hesitates whether to carbolicize his finger or not.

If the JOURNAL is unable to stimulate our faith, it should at least be careful in its *résumé* of facts.

DRESSER.

LETTER FROM LONDON.

MR. EDITOR, — Lately there has been quite a calm in the atmosphere of medical gossip here. A paper by Mr. Knowsley Thornton, One Hundred and Seventy-Two Antiseptic Abdominal Sections, With Remarks on the Causes of Death in the Fatal Cases, read before the Medical Chirurgical Society, provoked an expression of the most opposite opinions, regarding the value of the antiseptic conduct of such cases, upon which the author laid great stress. It was his habit to ligature the pedicle with catgut, to accurately adjust the edges of his wound, which he dressed with carbolized gauze, and did not disturb for nine days when he almost invariably found complete union. During the operation he practiced all the antiseptic precautions as most recently improved by Professor Lister. Mr. Thornton furnished a tabulated statement of one hundred and fifty complete ovariectomies, five incomplete ovariectomies, three exploratory operations with simple removal of fluid, eleven hysterectomies and abdominal sections for removal of uterine tumors, and three other abdominal sections, all performed antiseptically.

I enclose, for your use when treating of the special subject, the tables, which show fifteen deaths amongst the complete ovariectomies, and contain so many details of importance that it is impossible for me to attempt to do them any justice by summarizing. They will be worth looking for in the transactions of the society. Mr. Thornton was strongly commended for the frank and complete manner in which he had tabulated his experience, the practice of combining oophorectomies with ovariectomies in tabular statements, was strongly misadverted upon, as distinctly operating to destroy the whole possible value of statistical deductions therefrom.

It was pointed out that unfortunately tabular records of ovariectomy, originally schemed to furnish reliable statistical information, had been perverted from their legitimate use and been employed as data for the comparison of different operators' success. An abuse which had created a temptation, in too many instances greater than the operators could resist, to reduce the percentage of mortality by selecting the cases for operation, so as to exclude those which from their nature were calculated to prove hazardous. Mr. Thornton had not heeded the voice of the charmer, and one of his favorable critics, in commenting upon this, suggested that it would be fairer were the preëminently fortunate ovariectomists to add to their fatal cases, after operation, all those victims of ovarian disease, and avowedly fatal complaint, whom they left to die, rather than treat by the knife, — such patients necessarily dying without the chance of operative relief, or obtaining that at the hands of some less preëminently fortunate, but possibly less selfish and more humane, operator, whose statistics, as regards mortality, they must necessarily damage. The subject, as usual, afforded the ladies' doctors a grand opportunity for controversy, of which, as is their wont, full advantage was taken, and in a manner, too, which happily is not usual here amongst the practitioners in other special departments; for, not satisfied with the thrashing out of the subject before the authoritative society above named, some rushed into correspondence in the medical press, and thereby

endeavored to draw their opponent. But he maintained his own dignity, and that of the society before whom he had honorably laid his experience, by returning no answer. For, will any lovers of truth doubt that no good purpose can be served by endeavoring to continue the discussion, without the possession of additional facts, immediately after, or indeed while such a subject is before a scientific and authoritative body. A certainly ludicrous, if not indeed novel, argument was deduced from one opponent of antiseptics, after he had apparently almost exhausted himself, and yet was still unwilling to sit down before he had stated the overpowering evidence of the pyrexia due to antiseptic surgery, afforded by the assertion that since the introduction of the hobby into the Samaritan Hospital the consumption of ice had arisen to upwards of seventeen thousand pounds per annum, whereas previously "the matron used to have what was required from round the corner." This original pleader indicated that this mass of ice had been used for the ice cap, which had been needed to counteract the pyrexia developed through Listerism, but did not favor the society by stating for whom the ice cap was most needed.

At the Ophthalmological Society, on the 13th inst., a paper was read on Hypo-cleeral Cyclotomy, but it would not be fair to draw any deductions from the very limited experience quoted by other members than by Mr. Walker himself; whose remarks indicated him to be a believer in Dr. Brailey's hypothesis regarding the causation of glaucoma and a skeptic as to Mr. Priestly Smith's explanation of the same phenomena, except in perhaps a few rare cases. Under the title A Rare Form of Muscular Asthenopia, Dr. Brailey furnished a paper, giving elaborate details of the pains he had expended upon a slightly astigmatic patient, whose asthenopia was not relieved until a vertical dyslopia was discovered and compensated for by the wearing of a prism of three degrees. The president, Mr. Bowman, mildly suggested that he had met with very many similar cases, but had not usually found that they were relieved by prisms. Mr. Cooper made the practical suggestion that what Dr. Brailey had prescribed for his patient would only obviate the effect, whereas the practice of gymnastic exercise of the defaulting muscle, as recommended by Dr. Dyer, of Spitzberg, with the prism reversed, would often cure the cause of the trouble.

Mr. Hulke read a paper on Ophthalmoplegia Interna, and argued that disease of the ciliary plexuses in the choroid was a more tenable explanation of the phenomena, than to suppose, as Mr. Hutchinson had done, that they depended upon disease of the lenticular ganglion. Mr. Hutchinson replied, showing fully as much ground for his hypothesis as the author had opposed to it, and brought to his feet Dr. Gowers; who, in a most happy manner, suggested the much more feasible cause for the condition, namely, that it depended upon a disorder of the actual brain nuclei wherein the function was located. Physiologists had separated from one another, though they were immediately contiguous, the nuclei associated with the action of the extraocular muscles, those concerned in the pupillary reflex to light, and these again from those more anterior ones allied with the function of accommodation. The first of these, the most posterior, if diseased, would explain the phenomena of ophthalmoplegia externa, which was commonly syphilitic and unaccompanied by other nerve symptoms, and thus, supposing Dr. Gowers' hypothesis to be true, indicated the possibility of the posterior of

these cells being diseased without implication of their immediately anterior neighbors. Mr. Hutchinson's clinical experience had led him to consider that symptoms of ophthalmoplegia interna, the cause of which he laid upon disease of the lenticular ganglion, were strong presumptive evidence of syphilis. This clinical deduction might be considered as furnishing another link in the chain of evidence supporting the hypothesis of Dr. Gowers, that the symptoms depended upon an affection of the very particularized cerebral nuclei.

Mr. McHardy exhibited a specimen of hard glioma, confined to the optic chiasma, from a woman, aged thirty-six, whose symptoms dated back seven months, though vision had been affected for but less than half that period. The patient's vision was reduced to perception of light before she came under observation, no perimetry could be practiced; she was congenitally deaf, and the ophthalmoscopic appearances were just those so frequently met with in *tubercles dorsalis*, extreme blanching of the discs without diminution or tortuosity

of the vessels. Her gait had been reeling, with a tendency to fall to either side, probably in great measure owing to her defective sight; however, the case should tend to diminish the readiness with which one has of late been learning to diagnose cerebellar disease.

Dr. Williams, of Cincinnati, was unanimously elected amongst the first four honorary members of the Ophthalmological Society of the United Kingdom, a distinction which he shared with names respected no less than his own in the far-reaching circle of ophthalmologists, namely, Professors Donders, Helmholtz, and Hirschberg.

The very general interest in the of late predominantly important subject of Lister's antiseptic surgery has led me to visit King's College Hospital, where the system is to be seen in operation to its greatest perfection, but I have seen so much there, and have already so extended this letter that I must postpone a report until another mail day.

LONDON, January 15, 1881.

REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 29, 1881.

Deaths reported 2833; 1050 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 607, consumption 434, lung diseases 421, diphtheria and croup 236, scarlet fever 132, small-pox 63, diarrhoeal diseases 40, typhoid fever 34, malarial fevers 24, cerebro-spinal meningitis 23, erysipelas 22, measles 17, whooping-cough 10, puerpe-

ral fever six. From *diarrhoeal diseases*, New York 12, Philadelphia, Brooklyn, Chicago, and Boston four, Cincinnati and New Orleans two, St. Louis, Baltimore, District of Columbia, Buffalo, Nashville, Worcester, Fall River, and Quincy one. From *typhoid fever*, Philadelphia five, New York, Boston, Cincinnati, and Pittsburgh four, Chicago, Baltimore, and Spencer two, St. Louis, New Orleans, District of Columbia, Milwaukee, Cam-

bridge, Fall River, and Fitchburg one. From *malarial fevers*, Brooklyn six, New York five, Chicago four, St. Louis and District of Columbia three, New Orleans two, Nashville one. From *cerebro-spinal meningitis*, New York 13, Philadelphia three, Worcester two, Chicago, Boston, Cambridge, Haverhill, and Attleboro' one. From *erysipelas*, New York seven, Philadelphia five, Brooklyn two, Cincinnati, New Orleans, District of Columbia, Pittsburgh, Providence, New Haven, Lowell, and Springfield one. From *measles*, Boston five, New York four, Chicago two, Philadelphia, St. Louis, Cincinnati, Gloucester, Malden, and Spencer one. From *whooping-cough*, New York four, Philadelphia, Baltimore, Boston, Cincinnati, Pittsburgh, and Lowell one. From *puerperal fever*, St. Louis three, New Haven, Nashville, and Lawrence one.

One hundred and four cases of scarlet fever, 87 of diphtheria, and 20 of small-pox were reported in Brooklyn; small-pox, four in Pittsburgh; scarlet fever 41, diphtheria 13, in Milwaukee; diphtheria eight, scarlet fever one, typhoid fever one, in Somerville.

In 42 cities and towns of Massachusetts, with a population of 1,111,179 (population of the State 1,783,086), the total death rate for the week was 21.02, against 20.25 and 21.62 for the previous two weeks.

For the week ending January 8th, in 149 German cities and towns, with an estimated population of 7,660,002, the death-

rate was 25.5. Deaths reported 3749; 1734 under five: pulmonary consumption 583, acute diseases of the respiratory organs 345, diphtheria and croup 186, diarrhoeal diseases 115, scarlet fever 102, measles and röteln 57, typhoid fever 54, whooping-cough 46, puerperal fever 23, typhus fever (Danzig, Posen) two. The death-rates ranged from 12.7 in Darmstadt to 39.2 in Kiel; Königsberg 30.4; Breslau 28.7; Munich 30.4; Dresden 21; Berlin 23.3; Leipzig 21; Hamburg 24.1; Hanover 19.8; Bremen 20; Cologne 26.4; Frankfurt —.

For the week ending January 15th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 23.6. Deaths reported 3444: acute diseases of the respiratory organs 371, scarlet fever 99, whooping-cough 90, measles 74, diarrhoea 39, typhoid fever 35, small-pox (London) 27, diphtheria 19. The death-rates ranged from 13.4 in Brighton to 33.2 in Oldham; Sheffield 22.2; Birmingham 22.3; London 22.6; Leeds 22.7; Bristol 25.2; Liverpool 29.3; Manchester 32.4. In Edinburgh 23.1; Glasgow 24.1.

In the 20 chief towns in Switzerland, for the week ending January 15th, estimated population 522,856, there were 41 deaths from acute diseases of the respiratory organs, diarrhoeal diseases 13, diphtheria and croup eight, typhoid fever four, scarlet fever two, whooping-cough one.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.	
	Mean.	Mean.	Maximum.	Minimum.	7 A. M.	2 P. M.	9 P. M.	Mean.	7 A. M.	2 P. M.	9 P. M.	7 A. M.	2 P. M.	9 P. M.	7 A. M.	2 P. M.	9 P. M.	Duration.	Amount in inches.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM JANUARY 29, 1881, TO FEBRUARY 4, 1881.

VOLLEM, E. P., major and surgeon. Granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. S. O. 24, A. G. O., January 31, 1881.

BURTON, H. G., first lieutenant and assistant surgeon. Assigned to temporary duty at Fort Niagara, N. Y. S. O. 18, Department of the East, February 1, 1881.

SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a special meeting at 19 Boylston Place, on Saturday evening, February 12th, at seven and a half o'clock. The regular meeting will follow. Dr. A. N. Blodgett will read a paper entitled *The Collodion Treatment of Sprains*. Dr. B. O. Kinnear will open the discussion.

All members of the Massachusetts Medical Society are cordially invited to be present, and to join in the discussion.

H. C. HAVEN, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — Lectures on Syphilis, delivered at the Harvardian Society, December, 1876. By James B. Lane, F. R. C. S. Second Edition. London: J. & A. Churchill. 1881.

Objective Points in the Treatment of Phthisis. By William Porter, M. D. (Reprint.)

Table of One Hundred and Seventy-two Antiseptic Abdominal Sections. By Mr. Knowsley Thornton

Transactions of the Medical Society of the State of Pennsylvania at its Thirtieth Annual Session, held at Altoona, May, 1880.

On the Operative Treatment of Hare-Lip. By W. I. Wheeler, M. D. Dublin: Printed for the Author by John Falconer. 1880.

Proceedings of the Association of Medical Officers of American Institutions for Idiotic and Feeble-Minded Persons, Session at Barre, Mass., June, 1880. Philadelphia: J. B. Lippincott & Co. 1880.

The Development of the Osseous Callus in Fractures of the Bones of Man and Animals. By Henry O. Marcy, M. D. (Reprint.)

Photographic Illustrations of Cutaneous Syphilis. By George Henry Fox, M. D. Vols. IV., V., and VI. New York: E. B. Trent & Co.

A Manual of Diseases of the Throat and Nose. By Francke Huntington Bosworth, M. D. New York: William Wood & Co.

Cæsarean Section, with Removal of the Uterus and Ovaries after the Porro-Müller Method. By Elliot Richardson, M. D. (Reprint.)

Report of the Albany Hospital for the two Years ending January 31, 1880, with an account of the Hospital Bazar. Albany: Burdick & Taylor. 1880.

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties, January 1, 1881.

Annual Reports of the Managers and Officers of the New Jersey State Lunatic Asylum, at Trenton, for the Year ending October 30, 1880.

Elements of Practical Medicine. By Alfred H. Carter, M. D. Lond., etc., etc. Philadelphia: Presley Blakiston. 1881. (From A. Williams & Co.)

Lectures.

CLINICAL LECTURE.

DELIVERED BY PROFESSOR A. JACOBI, AT THE COLLEGE OF PHYSICIANS AND SURGEONS, OCTOBER 6, 1880.

THE first case which I present to your notice to-day, is that of Kate D., aged three years, whose history is as follows: About a month ago the child fell out of bed, a distance of perhaps eighteen inches, to the floor. Nothing unusual was noticed, immediately after this accident, but a week later, the mother, while putting on the child's shoes, observed that there was a swelling on the inner aspect of the left foot. Since then she says that it has not increased in size to any considerable extent, but has remained the same. At times the child complains of pain in the foot, more particularly, however, at first than at present. There is a swelling now over the head of the first metatarsal bone, and a slight swelling on the outer aspect of the foot, and the skin is slightly reddened. The child moves the foot pretty well, but there is marked fluctuation on the inner side, less on the outer. A small opening was made in the swelling last week, and some of the pus let out. This opening has closed again. Now if this abscess is the result of caries of the tarsal bones, why the case may remain in this condition six months, a year, a year and a half, the child may even lose the foot, and it is especially important, in the treatment, to take into consideration the intimate relations of the synovial sacs in this part of the foot with each other. The case must be treated antiseptically, and the incisions which shall be made from time to time small, so as to prevent the entrance of air. For a dressing afterward I shall order equal parts of water and Squibb's disinfectant. The disinfectant is a two per cent. solution of carbolic acid in water. The incision which I made a week ago has, as you see, healed up, but the abscess cavity has not been filling up very rapidly, and I shall make a second small incision to-day. If you had to make an opening in such an abscess fifty times a year, it is better to do so than to make too large an opening and so let in air. I squeeze out the pus, but very gently. It is a mistake to squeeze too hard. If you have made a small incision and then squeeze hard, to get rid of the contents of the abscess, you will only add to the existing inflammation. An incision into an abscess, when the admission of air is of no consequence, ought to be large. Then whatever is liquid will flow out of itself, without violent squeezing, and if there is pus not fully formed it will flow off in a day or two, but where we have to do with joints, as in this case, it is better to make a number of small incisions frequently, than to risk the admission of air. I cannot say all that I should like to in regard to this case to-day, as we have not time to go fully into it, because there are many waiting, but I shall bring the case before you again when I shall have an opportunity to speak further about it.

Our next case is Minnie S., aged nine years. Her mother tells us that about four weeks ago she noticed that the child could not pick up nor hold articles as well as usual. If she attempted to pick up anything she was likely to drop it immediately. This state of things was noticed on the right side first, but soon afterward extended to the left side of the body, and involuntary muscular twitchings appeared. The child

cannot now speak as well as before, because the muscles of the tongue are also affected. The mother says that she had a similar attack four years ago, but of a milder character. Her sleep is much disturbed at present because the muscular twitchings persist during the night-time, sometimes being so violent as to throw her out of bed. There is no tenderness along the spine. The mother says that the child has had "growing pains" quite frequently, but has never had rheumatism. There is present a mitral regurgitant murmur, however. Now the important points in this history to which I shall call your attention are these "growing pains," so-called, and the fact that there is a heart murmur present. The large majority of cases of chorea minor depend for their origin on an endocarditis which results usually in mitral incompetency. The so-called growing pains which children complain of are either muscular or articular. In the large majority of cases they are articular, and occur in the hip, knee, or ankle, and have no connection whatever with the process of growing, which is physiological and not attended with any pain whatever. These pains of which this child complained were true rheumatic pains and nothing else. In this case, as often happens, these obscure sensations of pain were followed by an endocarditis, as a result of the rheumatism, and that endocarditis has brought about a mitral incompetency. When, then, you have such a group of symptoms as these, "growing pains," endocarditis, the chorea minor is the third member of the group and is dependent upon the other two. This girl has had chorea minor before and no doubt from the same cause. There is one point in her history that is peculiar, and that is the fact that she has had these convulsive muscular movements at night-time, so that, as a consequence, her sleep is much disturbed. This is unusual in cases of chorea minor. As a rule, it is only in the severe cases of the disorder that these muscular twitchings persist during the night. When they do occur they complicate the case very much, for if there is anything which will get this child over her trouble, it is sleep. When the rest is disturbed, as in her case, the children become anæmic and the slightest thing will throw them over. I have no doubt that there is hypertrophy of the right ventricle. I will percuss and see. As I draw the chalk mark on the skin you will see that the heart dullness extends to the right, beyond the sternum and beyond the mamillary line. There is, then, as I have said, hypertrophy of the right ventricle. In the large majority of cases of chorea you will find heart lesions. In fact, it is on former attacks of endocarditis that most of these cases depend for their origin. And now comes the important question. What are we to do for such cases? For general reasons, and as there is but little fever here, this child must take iron; not, however, those preparations of iron which act as vascular irritants, such as, for instance, the muriated tincture. I should rather give the subcarbonate, or the pyrophosphate instead, in doses amounting to twenty to twenty-four grains daily. She may also take digitalis, either the fluid extract, of which she will bear two to four minims during the course of twenty-four hours, or an equivalent amount of the tincture. To control the chorea itself there is that symptomatic remedy, arsenic, which does more than all the rest. She may take it in the form of either of arseniate of sodium or potassium; of Fowler's solution, if the potassium salt is chosen, three drops in water, after meals. This dose may be increased gradually to twice the amount, and more. It

is of the greatest importance that she should rest well at night, and to give her the sleep she so much needs I propose to give her fifteen or sixteen grains of the hydrate of chloral every night, even twenty-four grains in a single dose, if necessary. Of the bromide of potassium or sodium she may take fifteen to twenty-four grains.

CASE III. This child, nine months old, fell out of bed three months ago; and shortly after the accident, the mother says that she noticed a swelling on the child's back, which remained about the same until three weeks ago, when it increased in size, and during the past week the skin covering it has become of a purplish color. The swelling is now about the size of a goose egg. There was another abscess, higher up on the back, which opened spontaneously, and another on the inner side of the right leg, which is still there. There was also an abscess on the right arm, which broke, and is not healed up yet. The tissues around it are still hard. Here is a history, then, of a nine months' old baby, who has, for the last quarter of a year, been the subject of a succession of abscesses. Now there is some etiological connection between these abscesses; they must have all a common source; as, for instance, in the heart; for the heart may be the source of such abscesses when there are vegetations on its valves, as a result of endocarditis, which vegetations, becoming torn off and carried into the circulation, are lodged in various situations and give rise to the formation of abscesses. This condition might also be the result of a pyæmic process starting from one abscess. This is an important point; for it is in just this way this spontaneous pyæmia, as this is called, is developed in the very young, giving rise to just such a series of abscesses as this child suffers from, which apparently have no common etiological source.

The most innocent abscess may give rise, in the young, to a pyæmic process, which is the result of absorption of purulent matter, and the patient may die, as a consequence. I have seen embolism of the pulmonary artery, which resulted in a fatal issue, come from a varicose ulcer of the leg. When you open these abscesses it is not uncommon to find that immediately after one or two new ones start up in the vicinity, particularly if the first abscess is of a furuncular nature. This will not happen if you disinfect the wound, nor are you to cut too soon. Wait until the matter is near the surface and then, making an incision, disinfect so that no absorption can take place through your incision, which is a fresh wound. A coagulum of blood retained may decompose, and the septic material, being absorbed, may give rise to a fresh abscess; therefore you must be careful to disinfect the wound thoroughly with carbolic acid. You may use a much stronger solution than that used in the spray, — a ten, twenty, fifty per cent. solution, or sometimes I apply even the concentrated acid itself. If you do this, you will be safe. Last week there was no discolorization of the skin over this swelling; but there is now, as you see, which shows that the skin is participating in the inflammatory process. The wound must not be large which you make. If you allow a large quantity of pus to escape from its confinement you relieve a large number of blood-vessels suddenly from pressure, and a hæmorrhage into the sac may take place, from which future mischief may ensue. If the pus is evacuated gradually the pressure on the vessels lining the sac wall is slowly reduced,

and hæmorrhage is not so likely to take place. After your incision is made, you will adopt the usual antiseptic treatment.

CASE IV. W. L., aged two years, has the following singular history: At birth, as the presentation was transverse, the left hand being the presenting part, the attending physician performed version, during which operation the left humerus was fractured. This is something which not infrequently happens during version, even when the child is not rachitical; so there was nothing remarkable in that; but about two months afterward the child was somewhat roughly handled and the right humerus was said to have been fractured at that time. Again, when the child was six months old the left femur was fractured, and soon after that the tibia also, but no callus was recognized. After an interval of six weeks the left tibia was again fractured, and the left humerus has been fractured three times. During the first year the child was nursed at the breast. The two upper incisors appeared at the age of six months, and a few months afterward the lower incisors. The remaining teeth appeared afterward, in rapid succession, all being cut before the child was eighteen months old, but were poorly developed, and soon decayed. Now here is a child just two years old, who has been the subject of more fractures than you would expect to occur in an entire congregation during that period. The left humerus has united at an angle, as you see, an angle, I should say, of about 130°, with the concavity looking backward, and there is an immense convexity in the right humerus, but no angular deformity. The forearms are normal. The sternum is more prominent than it ought to be; the diaphragmatic portion is drawn inward. The child has sixteen teeth, of which eight are already decayed, which is very far from being the normal state of affairs. Soon after birth the child had coryza, and an eruption on the skin. There have been a number of fractures here, which are more frequent in the old than in the young; for the bones of a child do not fracture so easily, because they are more flexible and contain less earthy matter, but more organic, than do the bones of an adult. Why is it, then, that we have so many fractures in this child? When a bone has its normal constituents it will not fracture readily; but when it is very soft it fractures easily. This often happens in bones which are the subject of rachitis, and sometimes in that case the fracture is not complete, but only partial. There is an infraction instead of a fracture. The bone inside the periosteum will be bent only, or the periosteum, which is very soft, untorn itself, will hold the ends of the bone together, so that you will get no crepitation because the periosteum acts like a splint. Infraction or fractures like this still produce deformity, as you see in this case before you, even though well attended to from the start, because the diseased condition of the bone prevents proper repair.

From certain symptoms in this case, as the coryza, the decayed condition of the teeth, and the eruption on the skin, it is probable that this child has hereditary syphilis. Indeed, when rachitis is observed in the bones, at the same time that the teeth are soft, it is highly probable that the child is syphilitic, and when rachitis appears very early it is often nothing more than syphilis of the bones. It was George Wegner who first called attention to the fact that a softening of the costal ends of the ribs is, in almost every case, due to hereditary syphilis, and that the syphilitic and

the rachitical softening of the costo-cartilaginous junctions cannot be distinguished from each other.

When you see such a case as this you are to make a careful distinction between a rachitis which is due to syphilis and one which is not. There are, it is true, quite a number of such cases, which are due to syphilis; but that is not true of them all, and it is important that you should make the distinction; for in *bonâ fide* rachitis you would avoid mercurials, but when due to syphilis you must resort to mercurials if you expect to cure.

A CASE OF HYDROPHOBIA OF DOUBTFUL ORIGIN.

BY S. L. ABBOT, M. D., AND R. H. FITZ, M. D.

WILLIAM ROEDEL, aged seventeen, a confectioner by trade, born in Germany, a resident of Boston, entered the Massachusetts General Hospital April 24, 1879. He was of nervous temperament; but previous to the attack for which he had been admitted, his health had been usually good. Three days before entrance, after dinner, he fell asleep on a lounge, and slept several hours, until aroused by his mother. On awaking he was suddenly seized with severe pain in the abdomen (about the umbilicus especially), over the sternum, and in both legs, particularly in the thighs. He went to bed, but could not sleep. The pain through the following night was excessive. During the next day and night it continued, entirely preventing sleep. On the morning of the third day he, for the first time, had difficulty in swallowing. When food or drink was offered him he experienced a choking sensation even before it touched his lips, and the act of swallowing was very difficult. The general pain continued during the day and the next night; but on the following morning, the date of his entrance to the hospital, was somewhat mitigated. No history of any animal bite, at any time, could be obtained from the patient or the friends who brought him to the hospital. Five weeks before, the terminal joint of the ring finger of the left hand had been caught in the cogs of a machine at the shop where he worked, and the tissues were somewhat torn. The part healed readily, however, being disabled for two or three days only, and at the date of entrance was entirely well, being not at all sensitive to touch or compression.

At the time of admission the patient's face had a wild expression, the pupils were dilated, and after being put to bed he made frequent attempts to sit up; but on being spoken to sharply he desisted. When drink was offered him the muscles of deglutition of the mouth, face, and upper part of the body were thrown into violent spasmodic contraction. This was excited even when the cup was as much as three feet from him, and he immediately made an effort to rise, accomplishing it with a little assistance, but falling back again unless supported. Liquid given with a spoon caused choking and was swallowed only after the most determined efforts. There had been no nausea, vomiting, or salivation. The pain in the umbilical region was increased by pressure. There seemed to be partial loss of power of motion in the legs. Temperature 98.6° F., pulse 112. At eleven p. m. had potass. bromid. fifty grains, chloral, ten grains, and slept until

1.30. Restless until three a. m., when he had fifty grains of bromide of potass., and slept until morning. Drank four ounces of milk, with effort, twice in the night. Could take no solid food.

April 25th. Swallowed with less difficulty this morning, but still complained of pain in both thighs, mostly at the inside; none below the knees; while at rest there was no pain in the thighs. Pulse 80, of moderate strength. Tongue covered with a thin fur. R. Tr. belladonnæ five minims, potass. bromid. ℥i., chloral hydrat. gr. v. and beef tea fl. 3 iv. every two hours. During the following night he slept none, although he took forty-grain doses of bromide of potass. every two hours until five a. m. He swallowed in all eight ounces of beef tea with some difficulty. At the time of visit on the 26th he was somewhat delirious, the pupils being largely dilated, but sight unaffected. Pain in legs less, with loss of muscular power. Urine passed freely. Fanning excites shuddering spasms like those caused by drinking (as was shown by Dr. T. B. Curtis, who was examining the case with me), and precisely like those produced in sensitive persons by the cold shower bath, or wading into cold water.

During the afternoon the delirium increased, and swallowing became more difficult; and at five p. m. it was nearly impossible. He had had regularly every two hours tr. belladonnæ five minims, potass. bromid. ℥i., tr. valerian. ammoniat. minims xx., and had also, got down four ounces of beef tea at the same intervals, the last dose being swallowed only after a most violent struggle. During the following night the delirium was excessive, the patient shouting violently, and struggling to get out of bed, requiring constant restraint. He took two doses of fifty grains of bromide of potass. each, but refused more. He also swallowed in all eight ounces of beef tea. After 1.30 his violence was excessive, and the extremities became cold. At this time he began to spit white, frothy sputa.

April 27th. Patient very delirious, spitting frequently, and refusing food and medicine, struggling violently, in a great passion with his attendant, endeavoring to get out of bed. No power of motion in legs. On directing the attendant to loose his hold and firmly ordering the patient to be quiet he became more calm and answered questions, saying he wanted to get out of bed so that he might go home. On being offered a teaspoonful of beef tea he swallowed it without difficulty, but refused more, saying he did not want it. He complained of much pain in the throat, and, if raised in bed, in his back. At eleven a. m. a subcutaneous injection of one third of a grain of sulphate of morphia was given without any obvious effect. At two p. m. he was so violent that a camisole was put on. He shouted and raved all the afternoon. At 5.45 a subcutaneous injection of one half grain of sulphate of morphia and one grain of ergotine was given. At 6.30 he was much quieter, and the respiration was quite slow. After eight p. m. the delirium increased, and at eleven p. m. and 1 a. m. he had subcutaneous injections of one grain of ergotine. During the afternoon and evening he spat frequently, and at midnight frothed at the mouth. He continued more or less raving until he died at 2.30 a. m. of the 28th.

Woorara was not administered in this case, as it had signally failed in other cases of hydrophobia in the Massachusetts General Hospital.

After the death of the patient it was learned for the first time, from his brother, that he had been bitten

during the previous summer or autumn by a flying squirrel. Subsequently his mother confirmed the statement. She said that the boy, sometime during the previous year, on returning from a walk to Forest Hill, brought with him in his pocket a flying squirrel which he obtained there, and which he said he had taken from its young. The inference is that it was during the summer, and that the specimen was a female. When taken from the boy's pocket the animal was very much excited, uttering loud outcries, apparently greatly enraged, and bit one of his fingers very severely, until, in the words of his mother, the blood streamed down his hand. In spite of her earnest entreaty to let it go, he held it, however, until a box was obtained into which it could be put. Here it was left for the night, but effected its escape before morning. The bite readily healed in a day or two, and gave the boy no special trouble. He was represented by his mother as being a good-natured fellow, of exuberant spirits, and inclined to handle animals rather roughly. She said she had often remonstrated with him for his treatment of the family cat, fearing he might be injured by it. She had not known, however, of his ever having been bitten, except by the squirrel. Her account of the commencement of the patient's illness differed somewhat from that previously given by the patient himself and the friends who accompanied him to the hospital. She stated that for two years he had been subject to periodical headaches, more especially in the right frontal and temporal regions. On the afternoon of the previous Sunday, the 20th of the month, he was in great spirits, and caused much amusement by masquerading about the house dressed in his sister's clothes. During the evening he was taken with a severe headache, the pain passing down to his jaws, and having a neuralgic character. It became so intense that his mother gave him a large dose of brandy, and he subsequently slept. The next day a dentist extracted the right upper canine tooth, which it was thought might have caused the pain. The following night, however, the pain returned, and was only quieted by another large dose of brandy. It recurred on the next night, and was treated in the same manner with the same result. It was not until Wednesday, the 23d inst., that the severe pain came on in the abdomen, from which he was suffering when he entered the hospital.

There can be no question that the case under consideration was one of genuine hydrophobia. The initial symptoms in this affection vary very much in different cases, but were in the present instance not materially different from those sometimes reported. It certainly was not a case in which the fears or the imagination of the patient had anything to do with the symptoms, for so little importance had been attached to the squirrel bite that it seems to have been quite forgotten by the patient himself, and was only brought to the memory of his friends by persistent inquiry after his death.

Common rumor has frequently reported cases of hydrophobia as caused by bites and scratches from excited animals not afflicted with this disease. Most medical writers, however, give little credit to such stories, and as a rule they are rejected as unreliable. Cheifus, however, says, in his *System of Surgery*, "from numerous and careful observations it cannot be doubted that the bite of beasts much excited, or when disturbed during copulation, may produce canine madness." The question is surrounded with difficulties, par-

ticularly as well authenticated instances are given of hydrophobia caused by absorption of the virus by an abraded surface which had been merely licked by a hydrophobic dog. It has also been claimed that the disease may be caused by the bite of a dog while in heat but not rabid; and Dr. Hammond mentions two fatal cases which he had seen, one of them that of a child only three years old, in each of which the bite was inflicted by a bitch said to have been in this condition.

It may well be questioned, however, whether the squirrel bite had anything to do with the attack in the present instance. If it had not the case must be set down as spontaneous in its origin, or as caused by some infection not known to the friends of the patient and forgotten by himself. The confidential relations between the boy and his mother were such that it is not at all likely that he could at any time have been bitten by a dog without her knowledge.

The autopsy was made by Dr. R. H. Fitz, April 28, 1879, twelve hours after death. The dura mater showed no abnormal appearance, the vessels of the pia mater were universally injected. Sections through the substance of the brain showed abundant puncta vasculosa, and the gray matter of the convolutions in general was of a somewhat purple tint. Nothing abnormal was observed in the ventricles or within the substance of the brain. The medulla oblongata was found to be softer than normal, but was at once placed in Müller's fluid, without further immediate examination. Sections through the spinal cord showed no unusual appearances, nor was anything abnormal found in the membranes of the cord.

The examination of the heart showed nothing abnormal. The aorta was hypoplastic.

Both lungs were distended; and the left showed a considerable degree of interstitial emphysema. Small patches of ecchymosis were found throughout both lungs; they were most voluminous posteriorly where were two of the size of lemons, not dense but spongy. A section through one of these patches at the base of the left lung showed a central cavity, containing odorless gas, the walls of which floated in water as a brightly shreddy mass.

The pleural surfaces were intact.

The spleen was normal in size, of a dark purple color, the follicles indistinct.

Both kidneys were extensively injected, and occasional ecchymoses were found in the capsule.

The bladder was empty, its walls contracted.

The liver was of normal size, of a bluish color, and contained an unusually large quantity of blood.

There was post-mortem softening of the stomach with perforation. The mucous membrane of the lower part of the small intestine was ecchymosed in points and patches, without giving evidence of further alterations.

Portions of the brain and cerebellum, the entire medulla and the spinal cord, were hardened in Müller's fluid, and subsequently preserved in alcohol. The microscopical examination of these organs was negative for all parts with the exception of the medulla oblongata.

In examining the hardened brain and cord only trial-sections were made, while the entire medulla was cut into successive sections, in which were found the changes to be described.

These correspond very closely with those previously

met with in a case of hydrophobia reported by Dr. G. B. Shattuck and Dr. Fitz, in the *Boston Medical and Surgical Journal*, 1878, xcix., page 261.

Whatever difference existed was one of degree only, the milary lesions being much more abundant in the present case.

In the statement of the nature of these changes it may be said that they consist of minute circumscribed accumulations of small round cells, which have been not inappropriately called "milary abscesses." Furthermore large numbers of small round cells were found in the external coat of many of the blood-vessels, both arterial and venous, especially of the latter. Their number was often such as to form a dense mosaic, without there being any perceptible overlapping. It is desirable to allude to this fact, as the opinion has been expressed that the milary abscesses previously referred to were merely transverse or oblique sections through the walls of such altered vessels. Again, hæmorrhages were very commonly met with, either within the perivascular lymph spaces, as irregularly defined patches, or in the substance of the medulla, without any evident relation to the course of the blood-vessel. Although the blood-vessels, notably the veins, were often found largely distended with blood, and in certain instances to such an extent that the idea of a thrombosis was suggested, yet the absence of any secondary changes within the vessel, wall, or immediate vicinity, made it impossible to decide that such an engorgement with blood might not have been the result of conditions existing at, or immediately before, the time of death.

The topographical examination of the medulla showed that the hæmorrhages were most abundant at the lower end, just above the decussation of the pyramids. When the region of the olivary bodies was reached, the milary abscesses, periplebitis and periarteritis were the prominent features, there being but little evidence of hæmorrhage. The prevalence of the milary abscesses was greatest in that part of the medulla above the middle of the olivary bodies, corresponding with the nuclei of the vagus and hypoglossus nerves. They were found in considerable numbers still higher, in the vicinity of the nucleus of the abducens.

Their situation was almost wholly in the posterior portion of the medulla, mainly in the reticular formation along the roots of the vagi, among the fibres in certain instances, especially in the vicinity of the round respiratory bundle.

Two abscesses were found within the nucleus of the hypoglossal nerve, and two within the vagus nucleus. Abscesses were also found within the olivary bodies, at their anterior border. At the uppermost part of the medulla the abscesses were found on both sides of the raphè, between this and the fibres of the abducens nerves, also in the reticular formation between the facial and the abducens.

Although these collections of cells are spoken of as abscesses, it is to be doubted whether in all instances actual abscesses were present. The indifferent cells were usually separated from each other by certain distinct intervals, wider at the periphery of the accumulation than at its centre. Within such an agglomeration capillaries and ganglion-cells were sometimes seen, the latter presenting a homogeneously granular appearance, with distinct nuclei, giving no evidence of being isolated from the surrounding nerve tissue. Indeed, neither in ganglion-cells nor nerve fibres were evident changes

detected. It is to be mentioned, however, that such a statement can be regarded as only of relative value, as the examination of these constituents of the medulla was made only after the tissues had been hardened.

Attention may again be called to the absence of appearances of a colloid or granular degeneration, which could be regarded as in any way distinct from changes repeatedly observed in the examination of nerve tissues from individuals whose brains during life gave no evidence of disease. Colloid masses of a rounded shape are often found in abundance in such cases, and have always been attributed to changes occurring during the process of hardening. In reality gaps arise, often in great abundance, which become filled with a homogeneous substance, translucent, feebly refracting light. This substance becomes readily stained by hæmatoxyline but is dissolved when the section is placed in a solution of ammonio-carmin. The gaps remaining have a sharply defined border, in which no evidence of degenerative or inflammatory change is to be observed.

The lesions found in the two cases examined at the Massachusetts Hospital correspond so closely with each other, and with those met with by Gowers and Kolesnikoff, both in man and dogs, that for the present they are to be regarded in their situation as the essential alterations to be looked for in hydrophobia. They are readily seen, and may be stated as indicative of an acute bulbitis. As the milary nature of the agglomerations of cells is so striking, and as Leyden has already reported cases of acute bulbitis which differ in many respects from cases of hydrophobia, the hydrophobic form of bulbitis may be characteristically spoken of as an acute milary bulbitis.

With this anatomical diagnosis, if further investigation continues to corroborate the results recently arrived at, much will be gained with regard to a proper understanding of the pathology of hydrophobia. The nature of the symptoms points directly to important changes in this region, which pursue an active course during a very brief period, and the phenomena are such as may readily be referred to the irritation of certain of the nerve-centres which are supposed to have their seat in the medulla.

The obscure ætiology of certain cases of hydrophobia is well known, and the question has often been raised whether animal poison had ever been inoculated in certain instances. It is quite possible that an acute inflammation of the medulla may have as varied an ætiology as an acute inflammation of the kidney. As already stated an acute bulbar paralysis is recognized by clinicians, and has been found by Leyden to be associated with limited lesions in the medulla. The symptoms are sufficiently well characterized to enable the diagnosis to be made, although the origin of this affection is at present indefinite. In the acute milary bulbitis the symptoms are also sufficiently characteristic, and in certain cases the exciting cause may be held to be sufficiently apparent.

There are cases, however, where the bite of an animal, not known to be rabid before or after the biting, has been followed by the disease hydrophobia, and it may well become a matter of extremely practical interest to determine whether it is not possible for an individual to produce within himself an acute bulbitis by an intense fear of the symptoms whose nature he may be more or less familiar with.

Were this possible, the number of cases of hydrophobic bulbitis might readily become diminished, with

the exact knowledge that an individual might produce this lesion within himself without the inoculation of a specific virus. The same means which caused the disease might prove equally efficient in producing a cure.

The above suggestion has presented itself in connection with the observation of definite, not to say characteristic, lesions in the case of a disease whose existence has repeatedly been denied, and in which the etiology is somewhat obscure.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.

BY F. I. KNIGHT, M. D.

THE ASSOCIATION OF DISEASES OF THE HEART AND KIDNEYS.

THIS association has long been recognized, and the tendency now is to consider them both products of a general diathesis, a morbid condition of the blood, which fluid, after having remained in retirement, as it were, from all consideration as bearing upon the production of local organic diseases, is again assuming its proper place in pathological inquiry. The present status of the above subject is well shown by the writings of Drs. Mahomed and Fothergill, extracts from which appear below.

Dr. F. A. Mahomed¹ says that now that we have got the sphygmograph the time has come when the pulse must once again be studied accurately; a new class of diseases has been revealed to us, and a safe guide for their treatment has been afforded. It has long been a well-known fact that high pressure exists in the systemic circulation both in acute and chronic Bright's disease, but it has been very generally believed that this pressure is produced by the impeded circulation of poisoned blood, and that this poisoned condition of the blood is due to the imperfect elimination of the excrementitious material by the kidney. Thus, the sequence is supposed to be, first, diseased kidney; second, retained effete material in the blood; third, impeded circulation; fourth, the cardio-vascular changes characteristic of Bright's disease. This view makes the kidney change primary, the cardio-vascular secondary. Dr. Mahomed has tried to prove that this sequence of events should be reversed, namely, that a poisoned condition of the blood is the primary condition, that this produces an impeded circulation through the capillaries, and subsequently the cardio-vascular changes, while the bad blood produces a congestion of the excretory organs, that is, of the skin, mucous membranes, and kidneys, but especially of the latter. The arguments upon which this hypothesis has been based are as follows: (1) that high arterial pressure is found to exist before any sign of failure of the kidneys to perform their functions occurs; (2) that certain poisons are known to produce kidney disease, that these poisons produce high pressure in the arteries, while no symptoms of kidney failure are discoverable; on the other hand, the kidneys are often found to be excreting rather more than their usual amount. (3.) The condition of high pressure is found to occur in some young people in all other respects perfectly healthy, but liable to a certain class of petty ailments. Such patients have very often a family history of gout or Bright's disease, and if they live long enough will al-

most inevitably develop it in themselves. (4.) Far from the kidney disease being the primary condition, he finds that patients with primary kidney disease, such as is seen in surgical kidneys or scrofulous kidneys, even of the most advanced nature, do not have high pressure in their arteries, while patients with acute Bright's disease, if the poison be acute and temporary, may lose all signs of high arterial pressure during their recovery, even at a time when the kidneys are manifestly crippled, the urine being albuminous, and the solids deficient in amount.

Looking at the matter from this point of view, Dr. Mahomed has tried to prove that the high arterial pressure and the subsequent cardio-vascular changes are the primary and most important conditions to recognize, while the kidney symptoms are only secondary, and are not even essential conditions; thus certain cases occur, and are not very unfrequent, in which the cardio-vascular changes of Bright's disease are present, but in which no marked changes are discoverable in the kidneys.

Dr. Mahomed considers that chronic Bright's disease is caused by a condition of the blood or tissues which may be either hereditary or acquired. It may be regarded as a diathesis, the existence of which can be recognized by the condition of high pressure occurring in the systemic circulation produced by the increased resistance to the circulation of the poisoned blood in the tissues. It produces extensive anatomical changes throughout the body, but especially in the cardio-vascular system, the kidneys, mucous membranes of the lungs, and gastro-intestinal canal, and in the skin. It reveals itself during life by functional disturbance of one or all of these organs, but the disorder of any one may afford the chief clinical characteristics of the disease, and lead to an incomplete diagnosis, in which its true nature is frequently overlooked.

The chief clinical aspect under which these cases present themselves are as follows: (1.) There is what may be considered the normal state of the individual, or what he calls "health," his ordinary "every-day" condition. (2.) Failure of the heart due to high pressure in the systemic circulation or of the right side secondary to the lung changes. (3.) The disease may especially show itself by its effect upon the lung, producing bronchitis, asthma, and especially emphysema; not unfrequently it appears as pleurisy, sometimes pneumonia. (4.) The symptoms may all be referred to the brain,—vertigo, headache, loss of memory, sleeplessness, convulsions, coma, or apoplexy.

With the brain may, perhaps, also be classed those conditions which affect the eye and the ear, hæmorrhages into the retina or tympanum. (5.) The liver may appear diseased, either functionally or with portal obstruction and ascites, resembling cirrhosis, the result of capsulitis. (6.) The stomach and intestines may divert attention from the more serious malady, presenting symptoms of gastro-intestinal catarrh, dyspepsia of various kinds, vomiting, diarrhoea, or constipation. (7.) The kidney may give the leading symptoms, and some signs from it are perhaps more frequently present than any others except the cardio-vascular ones; the chief are polyuria, low specific gravity of urine, and the occasional presence of albumen.

In all of these conditions a high arterial pressure, as indicated by the pulse, is the only constant symptom, and will always lead to the recognition of the disease except when fever is present; for then the pressure is

¹ Guy's Hospital Reports, series 3, vol. xxiv., 1879.

reduced, and the pulse may become dicrotic. Among the tests of high pressure, Dr. Mahomed gives the following, to be applied to the sphygmographic tracing. A line must be drawn from the apex of the up stroke to the bottom of the notch preceding the dicrotic wave. No part of the tracing should rise above this line; if it does, then the pulse is sure of high pressure. The height of this notch is another good gauge of this pressure. The higher it is from the base line of the tracing the higher is the pressure; the nearer it approaches the line the lower is the pressure.

It is in the early cases, if possible before organic changes are produced, that we should seek to treat Bright's disease. It is only by watching arterial pressure that we can recognize the commencement of disease. To promote the excretions, diminish the ingestions, and strengthen the heart, appear to be the chief indications for treatment. Purgatives are perhaps the surest and readiest means of reducing blood pressure. Next to purgatives may be placed diaphoresis. Frequent warm baths, water packs, or Turkish baths, with a certain amount of vapor mingled with dry air, are invaluable. These latter require to be used with care, and their effect upon the individual watched. The diet is of course of very great importance, and the diet for Bright's disease has been clearly laid down by all writers on the subject as a non-nitrogenous one. Sweet wines and beer are always forbidden, and whiskey appears to be generally considered the least harmful form of alcohol. Simple rest in bed is a mode of reducing pressure by no means to be despised.

Digitalis is a drug which has a twofold action in these cases. It helps the heart, and is of the greatest value when there is any dilatation of that organ, and it also acts as a most valuable diuretic.

In treating the high pressure of Bright's disease, it is of the utmost importance to recognize the true cause of the disease, and to treat that. In cases where the pressure is so high or the symptoms so severe as to call for immediate relief, the lancet will always be our most invaluable remedy. Dr. Mahomed has seen the greatest benefit derived from bleeding in cases of dilatation of the heart, — of the left side as well as of the right. So also in so-called uræmia, either with or without convulsions, or to relieve the pain in aneurism, bleeding is a most excellent practice. The author believes that in cerebral hæmorrhage bleeding should almost invariably be adopted. Bleeding will not only reduce the pressure, and therefore further reduce the tendency to hæmorrhage, but it will also increase the coagulability of the blood.

Pulse of high pressure, as we now recognize it, was exactly the pulse which the old practitioners invariably bled, the *pulsus magnus durus et tardus*. Dr. Mahomed feels convinced that we cannot do better than to follow their example in this, for by this practice the lancet obtained its greatest triumphs, and established for itself the first place among remedies.

Under the title of The Gouty Heart, Dr. Fothergill has an exceedingly interesting chapter on this subject.¹ The association of changes in the heart and arterial system, with changes in the structure of the kidneys, has now long been recognized. James, of Exeter, observed it in 1817. His view was that subsequently announced by Bright, namely, "that the altered quality of the blood might so affect the minute and capillary

circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system," and hence arose hypertrophy of the left ventricle. Rokitsky recognized the fact that arterial degeneration, true apoplexy, and cardiac hypertrophy were found with chronic renal disease. In 1855 Traube published some writings on the connection betwixt chronic disease of the kidneys and changes in the heart. At first he thought the rise in the general arterial tension due to the contraction of the kidneys and obstructed renal circulation, but he soon gave up this hypothesis as untenable (though it is still given as his mature view by many authors); he then adopted the view of impeded arterial flow, and in 1872 he was fully acquainted with the views of George Johnson as to the thickening of the muscular walls of the arterioles. He held, however, that this muscular thickening was not found in all cases. In 1852 Handfield Jones described the fibroid change in the arteries, which he considered as not inflammatory. In 1867 George Johnson described changes in the walls of the arterioles, namely, a thickening of the muscular coat by which the blood flow was obstructed. In 1872 Sir William Gull and Dr. Sutton read a conjoint paper on Arterio-Capillary Fibrosis, that is, on a change which was a fibrous thickening rather than a hypertrophy of the muscular wall of the arterioles, and found along with renal fibrosis. They hold this is a general fibrosis in which the kidneys often share, but not necessarily so. They hold that "the contraction and atrophy of the kidneys are but part and parcel of the general morbid change. The kidneys may be but little if at all affected, whilst the morbid change is far advanced in other organs." Considering it unsettled whether the view of Dr. Johnson or that of Gull and Sutton be the correct one, Dr. Fothergill proceeds to describe the disease. The condition of lithiasis is the first link in the pathological chain. The blood is imperfectly depurated and the waste products of albuminoids undergoing retrograde metamorphosis are present in excess. It has been asserted, that the presence of such waste products excites arteriole contraction immediately (George Johnson), while others, as Traube and Ludwig, hold that the arteriole spasm is set up by the effects of the waste-laden blood upon the vaso-motor centre, by which general contraction of the peripheral arterioles is excited. To the finger and sphygmograph at once there is furnished evidence of high arterial tension. Hence follows cardiac hypertrophy. The bulk of urine is of great diagnostic value. When the arterial tension is high the pressure in the glomeruli of the kidney is great, and the flow in the tubuli uriniferi is swift. When the pressure on these thin-walled glomeruli is lowered the bulk of urine passed is small. Thus the free flow and large bulk of urine of low specific gravity which characterizes the early stages of Bright's disease contrasts in a striking manner with the small bulk of concentrated urine laden with lithates, and of high specific gravity, which is seen in cardiac dropsy. There are certain points connected with the cardio-vascular changes of chronic renal disease which are of great importance, and are worthy of description. One of these is the slow steady pulse so characteristic of this combined condition. Whenever the arteries are full the pulse is slow. We saw, in describing the innervation of the heart, that when the roots of the vagus nerve are flooded with blood the inhibitory fibres are thrown into action and the systole of the

¹ The Heart and its Diseases, with their Treatment. Second edition. Philadelphia: Lindsay and Blackiston. 1879.

ventricle is retarded. If any skepticism exists as to the association of the slow pulse with arteriole contraction in the mind of any reader, it will at once be dissipated by dropping five or seven drops of nitrate of amyl on a piece of lint or a handkerchief and allowing the patient to breathe it. In a few seconds the blush caused by the dilation of the peripheral arteriole is accompanied by a complete alteration of the character of the pulse; a slow, hard, incompressible pulse is exchanged for the rapid compressible pulse of pyrexia. In a few more seconds this passes away and the pulse is again slow and hard. In spite of the inhibitory action of the vagus fibres apoplexy is not uncommon. The blood pressure is constantly high in the encephalic vessels, specially in those who are intellectually active. Exacerbations of the abnormally high blood pressure are produced, among other causes, by contraction of the cutaneous capillaries brought about by the fall in temperature, and by a more than commonly waste-laden condition of the blood. The blood highly charged with nitrogenized waste excites further contraction of the arterioles with their hypertrophied muscular walls, and then follow apoplexy, angina pectoris, or, if the heart is both dilated and hypertrophied, palpitation. Hence the importance of a judicious regulation of the diet. Another rarer outcome of the high blood pressure of this disease is aneurism. The sustained high arterial tension leads to atheroma, which may be general or in patches. Disease of the aortic valves is common in the class of persons who acquire the gouty heart, and it is Dr. Fothergill's strong conviction that mitral disease of the chronic sclerotic, or contracting form, found in elderly persons, especially in the form of regurgitation, is also found with the changes now being described. The strain to which the aortic valves are subjected by the long-continued high arterial tension is now generally recognized as the cause of aortic valvulitis. Dr. Fothergill thinks that mitral valvulitis is produced in the same way. In estimating the prognosis of valvular disease, so associated, we must take care to remember that the valvulitis is not the commencement of the disease. We must recognize the valve mischief as part of a large general process of which indeed it is one of the later outcomes.

As a consequence of the waste-laden condition of the blood, a number of apparently morbid actions are set up in subjects of lithiasis, which are apt to be regarded as diseases *per se*, a diagnostic error which is serious, as it tends to lead the practitioner away from the real nature of the illness and its appropriate treatment. Whenever a patient is seen presenting the following indications of lithiasis, namely, a tense pulse, a loud aortic second sound, with a hypertrophied left ventricle (or, may be, dilated and hypertrophied both), and passing a considerable quantity of urine, specially getting up at nights to make water, or whose urine is often laden with lithates, — then it behooves the practitioner to bear in mind the condition of lithiasis, no matter what the peculiar ailment of which the patient may complain. Affections of the mucous membrane, as bronchitis, or diarrhoea; of serous membranes, as pleurisy, or pericarditis; skin affections, as eczema; muscular pains called rheumatism, neuralgia, osseous disease, or arthritis, all may be the direct outcome of imperfectly depurated blood, the condition known as lithiasis, or, as Murchison preferred to denominate it, lithæmia. Curious attacks of dyspnoea are not at all rare in the subjects of lithiasis.

Basham, who knew them well, called them "inexplicable." Niemeyer attributed them to œdema of a transient nature; but though this may be so in advanced cases of heart failure, the attacks are too sudden and too transient to be so occasioned in the early stages. They may be due to spasm of the pulmonary capillaries, or, more probably, to the disturbing effect of the waste-laden blood upon the respiratory centres. In sleep the respiratory centre acts less energetically than in the waking state, is to some extent depressed, in other words, and the waste-laden blood probably further depresses it, till an attack of dyspnoea is the result.

Space will not allow us to give further abstracts from this very interesting chapter, which occupies over fifty pages of an octavo book. The treatment of the gouty heart follows the pathology of it. There is the treatment of the early stage previous to heart failure; and the management of the later stage, when the failing circulation has to be included therein. The first point is to remember that the presence of nitrogenized waste, in excess in the blood, is the initial departure from health. Consequently, the dietary is of primary importance, and not one grain of nitrogen beyond the absolute wants of the system should be taken in the food. The dietary should consist of foods beginning with F, — fat, fish, fruit, and farinaceous foods. A lobster salad is the typical dish for the gouty man, with perfect digestion; without a powerful digestion it is poison, producing acute indigestion. The further indications of treatment of both stages are exhaustively treated.

(To be concluded.)

Hospital Practice and Clinical Memoranda.

KING'S COLLEGE HOSPITAL, LONDON; REPORT OF OPERATIONS.

EXTIRPATION of the larynx was performed on the 16th inst., by Mr. Pick, at St. George's Hospital, for malignant disease, in an adult who had been previously relieved by tracheotomy, but whose life was threatened by frequently recurring hæmorrhage. I hear that the patient has rallied most satisfactorily from the operation, which was performed under an anæsthetic administered through the tracheotomy tube, the wind-pipe being plugged. The entire thyroid and cricoid cartilages were removed, and the hæmorrhage was not formidable; this I believe to be the twenty-third occasion on which so complete an operation has been carried out. I subjoin notes, the result of my visits to King's College Hospital, where I found Prof. John Wood, with whom Professor Lister shares the chair of clinical surgery, and Professor Smith, the occupant of the chair of systematic surgery, as also all the operators there, equally convinced of the practical importance of the antiseptic method, though I could not gather that Professor Lister's hospital colleagues were completely in unity with him as regards his hypotheses relative to the grand revolution he has had the honor to introduce into the treatment of wounds.

Though King's College Hospital is small by comparison with many others in this metropolis, it is attended by a large number of students, furnished from the medical department of King's College, and would appear to possess an altogether exceptionally rich

field for pathological surgical experience. At least I should judge so as, when I resolved to note for you a week's operating there, I found myself saddled with an attendance on at least three days of the week, and as it happened on the particular one I chose with no less than four days, had I gone to the ophthalmic operations, which I did not do on learning that Professor McHardy adopted no special antiseptic measures, the rigid cleanliness alone excepted, in the conduct of his operations on the eye-ball itself, which he considers to be furnished by nature with more than a fanciful antiseptic guard, in the arrangement of the cilia and the lachrymal flow.

At Professor Lister's clinical lecture on Monday, January 10th, the first patient had been treated for hydrocele of the tunica vaginalis testis; the serous fluid had been drawn off, and a drachm and a half of tincture of iodine (*Edinburgh Pharmacopœia*) three times as strong as the tincture of the *British Pharmacopœia*, injected, to excite a smart inflammation in the sac. The professor said the tincture of iodine and the resulting exudation were absorbed, and the cavity obliterated; similar phenomena occurred in pleurisy and pericarditis. A very severe inflammation was necessary to insure such results, as hydrocele itself was a very mild inflammation, hence, without a sufficiently strong irritant no effect would be produced.

Support for the scrotum is essential during the inflammatory stage, which attains its height in from three to five days. The skin has a sympathetic blush, such as is seen around a tight stitch, when the tunica vaginalis is inflamed by the injection. Very little pain or inconvenience had been experienced by the patient, who was carried in, lest by any movement the exuded lymph should be "churned up" in the serum, and prevented from becoming organized. Such treatment is apt to be too severe for young children, in whom, fortunately, a radical cure may be effected by what is but palliative in the adult; hence a cure is usually effected by tapping antiseptically and applying to the skin some such lotion as vinegar and spirits of wine, of each a pint with a drachm of the chloride of ammonium.

Professor Lister next showed a woman, with a painless, fluctuating, mammary tumor, probably sero-cystic, and said that the cure of such cysts by incision with drainage, though ultimately successful, was very tedious; that chloride of zinc injection was more rapid but less certain in its action, whilst a treatment combining the two was infallible. "The tumor is soft, easily movable under the skin, therefore not likely to be malignant; it appeared rather suddenly three weeks before Christmas, and its subsequent increase has been insignificant. It conveys a distinct sense of fluctuation and elasticity, but it would be erroneous to consider these signs absolutely diagnostic of a benign growth, for many soft solid tumors, adenoid sarcomata, present similar characters, but, if serous matter escape when a puncture is made the disease is probably sero-cystic, whereas the escape of a jelly-like matter or blood favors the diagnosis of malignancy."

The tumor was then tapped with a trocar and canula; serous matter escaped; a probe was passed into the external opening, which was slightly enlarged, and a drainage tube was passed over the probe to the bottom of the wound. Antiseptic dressings were then applied, and the bandaging of an antiseptic breast dressing was demonstrated.

Professor Lister next discussed the case of a man with an ununited fracture about the middle of both bones of one fore-arm. The injury had originally been compound and comminuted, through the limb being caught in some weaving machinery. Another fracture sustained at the same time had united soundly. Some months previously the ends of the still ununited bones had been cut down upon and secured together with stout catgut by an efficient operator; the failure of this first operation was probably attributable to the use of catgut in place of wire, the former becoming dissolved or organized long before the purpose could be effected for which it had been applied in this particular case. Professor Lister said when a bone is broken across exudation takes place, followed by the formation of embryonic tissue, in which the bone is laid down. This naturally suggests the question, Why should embryonic tissue lead to the formation of bone in one case, and in another to the formation of new skin, as in a cutaneous ulcer?

In a common open sore, granulation tissue forms and leads to the production of blood-vessels and nerves in the centre with a formation of skin at the edges. There are two modern theories: (1.) That the formation of all kinds of new tissue is due to wandering amoeboid cells, undergoing change after their passage from the blood-vessels, in one case becoming the nuclei of blood-vessels and in another epithelial tissue. (2.) That these products are due to proliferation of already existing structures.

Professor Klebs has experimented on sores in a frog's foot, and proved that epithelium cells are capable of wandering about, and possess amoeboid movement. This is comparable with pleurisy from cancer, when there is first mammary scirrhus, which invades the whole gland; next the patient is attacked with pleurisy, and an autopsy reveals a tubercle of cancer in the subpleural tissue. There the cancer cells must have migrated from the infected mamma, through the thoracic wall, into the pleura, without apparently affecting the intervening structures.

After the production of the embryonic tissue, perfect rest of the parts is absolutely necessary for the formation of bone, as, if movement take place, softening instead of hardening goes on, and finally fibroid tissue appears, after which rest alone is powerless to induce the formation of fresh bone.

Professor Lister operated upon this ununited fracture on Friday, the 14th instant, when he practiced Esmarch's bloodless method, and explained the importance of using a flat rubber ligature for the *upper* extremity, where, from the scantiness of soft parts and exposed condition of main nerve trunks, paralysis was apt to result from the constriction of a cylindrical elastic cord, which was to be preferred in the case of the lower extremity, where an opposite condition of parts obtained. He cut down upon the fractured extremities of the bones, and working with a periosteum detacher, thoroughly denuded them, and removed from their immediate neighborhood a large comminuted fragment, which he had little doubt played no inconsiderable part in preventing union. He said there were three essentials to the osseous union of fractured bones: (1.) Absolute rest. (2.) Apposition of the fragments. (3.) The absence of any foreign body such as a comminuted portion might become, between the fractured extremities. He next fitted the ends of the bones to one another by removing from each, with

the saw, sufficient to adapt them in length and surface. The operation was completed by securing the fragments of each bone together with a loop of stout silver wire passed through holes drilled for the purpose. No vessels required to be ligatured on the removal of Esmarch's bandage, and the wounds were not sewn up, lest so doing should result in a confinement of the serum which must necessarily exude in such a case, and could not give trouble if allowed free vent; in a case treated antiseptically, Professor Lister mentioned that when he first filled a surgical chair his old teacher, the celebrated Syme, in a tone of condolence, regretted that there then remained so little more to be discovered in surgery; but how vast and important were the strides that the surgical art had since made, even as exemplified in the operation just completed. Professor Lister said, "Consider the steps of it, minus an anæsthetic, minus the bloodless method, minus the subperiosteal manipulation, and minus the security afforded by its thorough antiseptic conduct, all important facts culled since my student days!"

On Tuesday, the 11th inst., Professor Wood operated on two men for the radical cure of old irreducible inguinal hernia. In the first case the contents of the sac proved to be entirely omentum, so changed as to possess much the character of a fatty tumor. Professor Wood most carefully unfolded and dissected every portion of this omental mass, commenting, as he did so, upon the grave importance of not overlooking the possible presence of a small knuckle of intestine therein. He next secured the pedicle with stout carbonized catgut ligatures, which constricted the whole of it in sections before its amputation was accomplished. After removing this mass and a portion of the sac, he brought the sides of the canal together with stout silver wire sutures, disposed so as to invaginate some hernial sac and omental stump, and thus block up the canal. It was at least the twelfth time that he had performed such an operation with the removal of the sac and its omental contents, and had not then met with a death in consequence. He pointed out that for its safe performance the operation required an accurate anatomical knowledge of the whole neighborhood, complete arrest of all oozing before any parts were returned into the canal, and the avoidance of any portion of gut enveloped in omentum. He said, however, if in such a case a portion of gut were cut off the accident need be by no means fatal. With the injured gut so disposed that its contents could pass freely along the proper course, and a due vent afforded for any fecal escape from the intestinal wound, which might be stitched up with an ordinary glover's continuous suture, localized peritonitis might quickly isolate the mischief, and convert the case into a simple one of artificial anus. A condition which experience teaches is more easily cured than maintained. He alluded to the comparative immunity with which, under proper precautions, the parietal peritoneum could be manipulated, and attributed the old surgeons' dread respect for that membrane to a conservative servitude to the writings of Celsus, who quoted from a previous genius, stated that a wound of the fine membrane about the guts was fatal. Hence, Professor Wood emphasized the important practical point of differentiating between the visceral and parietal peritoneum.

Saturday, January 15, 1881, Professor Wood operated on a girl, aged eighteen, suffering from malignant disease of the humerus. The tumor, which had been

growing for six months, was so large that it was feared to have involved the scapula. The skin over the upper part of the tumor was glazed, thin, and looked as if implicated. Amputation at the shoulder joint was performed by short anterior and long posterior skin flaps. The tumor, though involving the supraspinatus, was removed without the scapula, and as the operator remarked, the patient's health was such as to preclude the more serious operation. The tumor proved to be a periosteal myelo-sarcoma. Professor Wood operated for the radical cure of an inguinal hernia, by the method which is described with his name in surgical works, and which he has himself practiced upwards of two hundred times without encountering a fatal case.

He treated a case of varicocele by passing a needle threaded with silver wire through the skin behind the veins, then bringing it round in front of them, and out at the point of entrance. The continuous tension of the loop, embracing the veins, was insured by adjusting the ends of the wire to a C-spring clamp, which was strapped *in situ*. In a child with extreme rachitic deformity of the tibia, he chiseled a wedge-shaped portion of bone out of the convexity of the tibia, and restored the limb to a normal position.

Professor Smith operated next. A case of necrosis of the head of the humerus, which had been treated by free incision and drainage, in the hope that exfoliation would complete a cure, was now submitted to excision. The head of the humerus contained a sequestrum of necrosed bone and a cloaca situated close to the cartilage; but both the scapular and humeral cartilages were unaffected.

A case of fistula in ano enabled the operator to demonstrate the tunnelings dependent thereon, which so frequently occur, and are overlooked. He slit up five such and plugged the wounds with lint.

Mr. Bell treated a varicocele by the compression of two elastic bands, which he passed before and behind the veins by means of a cannula, and after putting the bands on the stretch clamped them together with lead plugs at the entrance and exit wounds, so that the compressed veins should ultimately be ulcerated through.

LONDON, January 24, 1881.

Reports of Societies.

WINTER MEETING OF THE COUNCILORS OF THE MASSACHUSETTS MEDICAL SOCIETY.

THE winter meeting of the councilors of our state society was called to order at eleven o'clock, February 2d. The president, DR. HENRY W. WILLIAMS, in the chair.

The first business in order was the customary reading of the records of the last meeting by the secretary.

The president then mentioned the names of the committee he had appointed to confer on the petition of the Norfolk District Society for a new act regulating the commitment of the insane to hospitals. His nominations were confirmed.

The decease of Drs. David P. Smith, late vice-president of the society, James C. Dorr of Medford, D. W. Burleigh, of Lynn, and Ebenezer Alden of Randolph, probably the oldest member, was next reported, with eulogistic remarks.

The president read the names of delegates to other state societies, and then appointed Drs. Edes and B. S.

Shaw as committee to audit the treasurer's account, Drs. Langmaid and Rotch to examine the library, and re-appointed Drs. Hosmer, Millet, and Presbrey as committee to examine the by-laws of district societies.

DR. CHARLES D. HOWANS, chairman, then read the report of the committee on finance, recommending that the dues of four delinquent Fellows who are able to pay, but decline to do so, be collected by legal process. The recommendation was accepted. Cases in which remittance of dues was suggested because of age and poverty were referred to committee on membership and resignations.

The report of the committee on membership, DR. J. AYER, recommended that certain Fellows be allowed to retire. Accepted. Also that one Fellow be dropped for non-payment of dues for five years.

DR. F. I. KNIGHT, of Boston, asked upon what principle the council sues one man and drops another.

DR. AYER replied that this may be explained by means of the five-year law, which allows the society to drop a man in certain cases the circumstances of which requires this course in preference to another.

DR. FRANCIS, of Worcester, asked for a reply to the frequent and heretofore unanswered question: When a man is dropped does he cease to become a member?

DR. MINOT explained by saying that when a man is dropped the society rids itself of a scallawag, who disappears below the surface and never reappears. In the case under consideration the man's refusal to pay his dues and his indifference requires legal proceedings.

DR. BOWDITCH asserted that the council has no right to expel a man. This is a duty of the committee on membership.

DR. MINOT replied that a dropped man is not expelled; his name is simply omitted from the catalogue.

The president then said that delinquent members may be dropped by a law of some years' standing.

DR. AYER then read this by-law, which is as follows:—

(SECT. 7.) "Any Fellow who has not paid an assessment to the society for five consecutive years, and who, after due notification of his delinquency, neglects, or declines, without sufficient excuse, to pay his dues, may, on report of the committee on membership and resignations, be dropped from the roll of Fellows by a vote of the councilors."

DR. LYMAN asked why a delinquent should not be sued.

DR. DRAPER, referring to the case under discussion, said the man was bankrupt in morals as well as in purse. To sue him would be useless. To drop him is an easy manner of relieving the society of an unworthy member.

DR. CUSHING (Norfolk District), chairman of the committee on the petition of the Norfolk Society for an act relative to treatment of the insane by the public authorities prior to their commitment to asylums, now read their report, which was embodied in—

"An Act with regard to the commitment of insane persons to hospitals for the insane.

"SECT. 1. The superintendent of any public, private, or corporate hospital for the insane may receive for custody and detain therein for any period not exceeding three days, and without any order of judge or justice, any person as insane whose case is duly certified to be one of emergency by two physicians qualified by law to sign certificates of insanity in this common-

wealth; and at the end of three days, or earlier if need be, any insane person so detained shall be discharged, unless committed according to law by the proper judge or justice.

"SECT. 2. It shall be lawful for the superintendent of any insane asylum to entertain and keep in such asylum, as a boarder and patient, any person who is desirous of submitting himself to treatment, but where his mental condition is not such as to render it legal to grant a certificate of insanity in his case: provided, always, that such boarder shall make written application for such treatment, and that he shall not be detained for more than three days after having given notice of his intention or desire to leave such asylum, unless a certificate of insanity, signed by two qualified physicians, and an order from a judge or justice have been obtained.

"SECT. 3. One of the physicians signing a certificate may be an officer (medical) in connection with an insane asylum, provided the person certified to be insane is sent to an asylum with which such physician is in no way connected.

"SECT. 4. All acts and parts of acts inconsistent herewith are hereby repealed."

The report concludes as follows:—

"Voted, That the bill as proposed be adopted, and that it be referred to the councilors as the recommendation of the committee."

"Voted, That in regard to the alleged too easy commitment of patients to insane asylums, and the too easy discharge therefrom of insane criminals and paupers, the committee have no recommendation to make."

DR. CHARLES F. FOLSOM, secretary, stated that the 31st day of January would be the limit of the time set for the introduction of new matter before the legislature, and that, therefore, at his request, Senator Crocker had proposed an amendment to the law regarding the commitment of the insane to hospitals, which will give the councilors opportunity to be heard.

DR. MILLET, vice-president, mentioned insane paupers who were not properly protected. One was that of a young woman temporarily deranged who was sent to the Danvers Asylum, but who from motives of economy was taken away by the authorities of her town and sent to an almshouse. Another case now in an almshouse is refused admittance to the asylum by the overseers of the poor. He thought such cases of equal importance with those mentioned in the bill, and that they should be included before it goes to the legislature.

DR. FOLSOM admitted that there was a certain amount of justice in the criticism, but the cases are those which can hardly be touched by the council. Our asylums are filling rapidly. These pauper cases could be better managed elsewhere by friends who would undoubtedly be able to pay \$1.50 per week for their board in the almshouse. Board in the asylums costs \$3.50, and they are too full to take these harmless cases which can be cared for just as well in an almshouse as in an asylum. In regard to cases removed from the asylum: this is always done with extreme care. If anything the mistake consists in discharging too few rather than too many. There are so many cases that the difficulty of decision in some is great. In the very case quoted by Dr. Millet it seems to have been better to send her to the almshouse where she was cared for properly.

DR. MILLET thought the case so unjustly treated

that he took the woman to his own house. An overseer had applied for her discharge from the asylum, and it was done forthwith. If treatment in the asylums is not humbug, discharge should be decided judicially and not hastily.

The president mentioned cases which were turned from the doors of the asylum and consigned to a lock-up because no legal commitment had been made. One patient on the approach of officers cut his throat, and others in acute mania were made worse by this form of management.

DR. LYMAN hoped Dr. Millet's suggestion would be added to the report. But it was then moved that the report be adopted in its present form, and the motion was carried without opposition.

DR. MILLET moved that the same committee be requested to bring the matter to the notice of the legislature.

On motion of DR. BEACH, of Boston, Dr. Millet's proposition was amended by the addition of the president to the committee.

The motion was then confirmed.

SECRETARY GOSS read a communication from a physician of Rockport in relation to legal steps taken to secure his dues. This Fellow thought the demand of the treasurer emphatically unjust in principle, because he had never been notified of meetings nor called upon for annual fees until notice had been given the treasurer by another member, and then came a demand for fees for the two years during which he was practically unrecognized.

DR. DRAFER, the treasurer, on being asked for information, moved that the communication be laid on the table and the petitioner be given leave to withdraw. He had exaggerated his position. Having become a Fellow many years ago he went West, and there is no record of his ever having withdrawn from the society. He can therefore be held for \$118. Disappearing for years, he reappeared in 1875 and asked for readmission. The treasurer had a letter from him acknowledging reception of the notice of his readmission. As to the annual notices the treasurer knew nothing, but they do not affect the man's duty. If members were to complain of lack of attention, non-reception of society notices, etc., the committees would have a busy time. No Fellow seemed to know anything of the petitioner, not even members of the society of his district.

DR. C. D. HOMANS remarked that there is no rule which obliges the society to send notices before dues are paid.

(It might have been added that even life insurance companies send notices that premiums are due only as a courtesy, and do not hold themselves liable in case such notices are not sent to policy-holders.)

SECRETARY GOSS did not know the petitioner had any reason for complaint. His name may have been overlooked, but he doubted it.

By vote the petitioner was given leave to withdraw.

The secretary then read a communication from the censors of the Suffolk District Society and of the society at large calling attention to the need of greater uniformity in the examination of candidates. Since the division of the society inquiry discovers that some boards of censors exact almost no examination from candidates. The communication therefore asked for action in the matter.

DR. SHATTUCK thought this a very important subject. He did not believe that with seventeen boards of censors there can be uniformity. A candidate will be rejected by one board and passed by another. He thought that to have so many boards of censors was a great mistake.

By a vote of the council the matter was referred to a committee of five nominated by the chair, namely, Drs. Hosmer, Paddock, Nickerson, Dudley, and Bradford.

Names of gentlemen proposed for honorary membership were then read, and referred to the committee on membership.

The treasurer announced that in his will the late Dr. John Clough, of Woburn, left the sum of \$100 "to be expended for three of the best papers on the treatment of disease by moral management *versus* medicine or drugs." The amount is to be awarded in sums of \$50, \$30, and \$20 respectively, Drs. Bigelow, Ellis, and Harlow to be the committee of award.

Accepted by vote, and the secretary requested to announce the subject for competition.

DR. S. L. ABBOT on behalf of Dr. H. I. Bowditch read a motion proposing that women shall be admitted to examination as candidates on equal terms with men.

DR. BOWDITCH referred to the history of the movement and the reconsideration of the vote of the council, and thought as a matter of pride the Fellows of the council ought to know their own minds too well to adopt the suggestions of the censors of one district society.

The president then gave full details of the movement, and closed by reminding the council that the censors offered their protest simply because they found they were incurring the danger of a heavy fine in case they examined women under the present condition of the by-laws, and therefore asked a reconsideration of the vote which admitted women to examination. The council saw the justice of this, and voted to reconsider their vote. The question then remains as it did at first.

DR. PINEO, of Hyannis reminded the council that the annual meeting of 1880 adjourned to a definite hour of the afternoon preceding the next annual meeting for the discussion of this question.

The president admitted the adjournment, but stated that Dr. Bronson, the mover, though he mentioned this question, did not in his motion include the subject for discussion at the proposed meeting.

DR. SHATTUCK expressed the opinion that the question is a pernicious matter, and that the minority is a large one. He thought that to bring up such a subject at our centennial meeting would only disturb the peacefulness of the occasion. He read a letter from a former Fellow who voted women into the Chicago Medical Society. The result was no further protest from the minority, but a quiet and gradual loss of interest on the part of influential men, who finally ceased to attend meetings, and the gentleman himself heartily regretted his vote.

DR. BOWDITCH did not know that the society met for the mere purpose of harmony. He had no especial wish to admit women, but when a woman of ability with whom he had consulted for thirty years comes and says, "I want recognition from the Massachusetts Medical Society," he knew not how to object. The Boston University turns out homœopathic women, the Harvard Medical School refuses to admit women, and

the university admits them only to the annex. The result will be hordes of half-educated medical women. The question ought to be considered for justice's sake.

DR. LYMAN moved that the matter be laid on the table, and said: We are in harmony. The society never stood higher and never worked more smoothly. Our next meeting will be centennial. At least one half the society feel strongly against the admission of women. If the members were to go into the New York society, presided over by a woman, and listen to discussions by the strongest men of that body, he would come home feeling glad that women were not in ours. Justice has two sides. We have a right to consult with women if they be properly educated, but let us not bring up the objectionable question of their admittance here.

In regard to consultation with women it was shown that the by-laws do not forbid it unless the women be imperfectly educated or are indulging in practices forbidden to the Fellows. No member would wilfully consult with uneducated females. If by error he did so, he would undoubtedly be willing to apologize to the society.

DR. LYMAN, being requested by Dr. Francis to withdraw his motion, in order to admit a remark, declined to do so.

The question was then called, and received a strong affirmative vote, thus tabling the subject.

DR. WELLINGTON offered a motion to this effect: *Voted*, That a plurality vote shall elect officers of district societies.

The president expressed the opinion that in this matter the council had no right to interfere with the branch societies.

DR. WELLINGTON said a discussion had arisen as to whether a majority or a plurality vote would elect, and hence his motion.

DR. SHATTUCK moved that the question be referred to the proper committee for consideration. *Voted* in the affirmative.

The president proposed to refer the subject to the committee on by-laws, if agreeable to the council. *Affirmed* by vote.

The meeting then adjourned.

ANNUAL MEETING OF THE NEW YORK STATE MEDICAL SOCIETY.

THE Medical Society of the State of New York met in Agricultural Hall at Albany, on Tuesday, February 1st, with the president, Dr. W. H. Bailey, of Albany, in the chair. Among the papers read on the first day of the session were the following: *Neuro-Retinitis*, by Dr. David Webster, of New York; *The Significance of Facial Hairy Growth among Insane Women*, by Dr. A. McLean Hamilton, of New York; *A Contribution to the Pathology of Orbital Tumors involving the Bones of the Orbit*, by Dr. C. S. Bull, of New York; *Nasal Stenosis*, by Dr. J. O. Roe, of Rochester; *The Transplantation of Large Pieces of Skin without Pedicle*, by Dr. Arthur Matthewson, of Brooklyn; *Medical Induction Coils (with exhibition of instruments)*, by Dr. L. E. Felton, of Potsdam; *On Dressing the Umbilical Cord*, by Dr. Daniel Lewis, of New York; *Perichondritis Auriculæ*, by Dr. T. R. Pooley, of New York; and *The Surgical Treatment of Epithelioma of the Cervix Uteri*, by Dr. W. W. Potter, of

Batavia. The reports of the treasurer and librarian, and of the Merritt H. Cash prize essay fund were also read, and Dr. O. D. Pomeroy, of New York, exhibited a new aural and throat mirror and a modification of the ear syringe.

The committee on legislation made its report; a considerable portion of it being devoted to the question brought up by a resolution recommended to the consideration of the State Society by the Broome County Society, which urged the regulation of the dispensing of medical charities, and suggested that a committee of the State Society should ask the legislature to require all institutions receiving state or municipal aid to restrict the admission of patients or the dispensing of medicines or treatment to those only whose pecuniary circumstances instantly demand assistance. The committee, while it believed that the proposed legislation would prove of great service in controlling the evils connected with the present system in the rural and sparsely settled portions of the State, did not believe that it would be of equal benefit in the larger cities, and were not, therefore, disposed to favor the passage of the general act, as proposed. In the evening, Dr. William Hailes, Jr., of the Albany Medical College, delivered a lecture before the society entitled: *A Plea for More Practical Work in the Laboratories of our Medical Colleges*, which was illustrated by means of the stereopticon.

The following papers were presented on the second day: *Litholapaxy, with entire Removal of Fragments at same Sitting by Bigelow's Aspirator*, by Dr. N. L. Snow, of Albany; *Thoughts on Sanitation*, by Dr. Harvey Jewett; *Cicatrical Contraction of the Thumb, Fingers, and Palm of the Hand, resulting from a Burn*, by Dr. Alfred C. Post, of New York; *Hysterical Vomiting in Pregnancy*, by Dr. J. C. Warren, of New York; *Medicinal Eruptions*, by Dr. H. G. Piffard, of New York; *The Administering of Nitrite of Amyl*, by Dr. H. G. Piffard; *Inter-Parietal Hernia*, by Dr. George F. Shady, of New York; *Exostosis of the Frontal Sinuses*, by Dr. H. Knapp, of New York; *Vesical Calculi, with Operations*, by Dr. A. Vandervoort, of Albany; *Double Talipes Equino-Varus*, by Dr. A. M. Phelps, of Chateaugay; and *Early Diagnosis of some Organic Diseases of the Nervous System*, by Dr. E. C. Seguin, of New York.

Dr. A. Jacobi, of New York, vice-president of the society, read a report on the care of children, which was referred to a committee with instructions to confer with the Society for the Prevention of Cruelty to Children, in regard to certain points embodied in the report. Dr. J. C. Dalton, from the committee on experimental medicine, presented a report in which reference was made to the steps taken by Mr. Bergh to procure the passage of an act prohibiting vivisection, and it was voted that the secretary should transmit to the committee on public health of the legislature the objections of the society to its passage. A motion by Dr. Post that in the sense of the society the bill should not be made a law was unanimously adopted by a rising vote. Dr. E. V. Stoddard, from the committee on hygiene, reported that after consultation with the State Board of Health it had been decided to make diphtheria the special subject of consideration, and made a statement of the work that had been done in this direction. Dr. Elisha Harris, secretary of the State Board of Health, expressed the hope that the committee on hygiene would persevere in its inquiries in regard to diphtheria.

and other contagious diseases. During the month of January, he said, fifty towns had reported the prevalence of diphtheria and forty-eight the unusual prevalence of scarlatina.

The committee on the president's address in its report recommended that three of the suggestions of the president (Dr. H. D. Didama, of Syracuse, president last year) should be adopted. As to the first, that the profession should coöperate with the State Board of Health, the committee recommended the adoption of a resolution that county medical societies be requested to instruct their committees on hygiene and public health to place themselves in communication with the State Board of Health. The second suggestion was in reference to certain proposed changes in the examinations or the degree of Doctor of Medicine in this State, and the committee recommended that the committee on legislation should be instructed to take the necessary measures to secure the amendment of the existing law in order that these might be carried out. The third suggestion was that such changes should be made in the code of ethics as would enable it better to conform to the present wants of the profession, and the committee recommended the appointment of a special committee of five to report upon the subject in 1882.

In the evening the annual address of the president was delivered in the assembly chamber at the Capitol. It was of a general character, and among the topics touched upon were: the importance of preliminary training before entering upon the study of medicine; the advantages of a thorough drill in the fundamental principles of the latter; the duty of the physician to instruct the community in sanitary science and prudence; the social and moral relations of the medical man; the functions and objects of medical societies, and the value of the latter to the community at large. After the president's address the annual banquet came off at the Delavan House, at which the usual toasts were responded to.

On the third day several biographical sketches of deceased members were read by titles, and Dr. James Chapin, of Medina, presented a paper on A Case of Cystic Degeneration of the Chorion. Clark Bell, Esq., of the New York Medico-Legal Society, then read, by invitation, an elaborate paper on Reforms in Regard to Coroners' Offices, which treated of the many abuses which exist under the present system of making autopsies and in the selection of coroners in New York city and elsewhere throughout the State. The paper was discussed at some length, and, on motion of Dr. Squibb, of Brooklyn, it was referred to the publication committee, with a recommendation that it be published, and also to the committee on legislation, with instructions to confer with the representatives of the Medico-Legal Society in reference to the matters contained in it. The president announced the following committee on Revision of the Code of Ethics, as ordered by the society in accordance with the suggestion of the annual address of last year: Drs. William G. Wey, C. R. Agnew, W. S. Aley, H. G. Piffard, and S. O. Vanderpool. The following papers were then read: A Device for Retaining Dislocations of the Clavicle at its Distal End, by Dr. C. L. Stiles, of Oswego; and The Benign Aspect of Syphilis, by Dr. George H. Fox; after which Dr. Lewis Bulch, of Albany, read a review of the second trial of Jesse Billings, Jr., for the murder of his wife, in the course of which he explained the tests made of the effects of

gun-shot injuries of the human skull, and exhibited a number of skulls which had been experimented upon, as well as that of the murdered woman.

A resolution was adopted urging the various county societies to endeavor to secure the coöperation of the other incorporated and district medical societies throughout the State in the enforcement of the "Act to regulate the licensing of physicians and surgeons," passed May 29, 1880, and also one to the effect that in the opinion of the society it was desirable for the legislature thoroughly to amend and revise the laws of the State in regard to the office and duties of coroner, and recommending for their consideration the recent statute adopted by the State of Massachusetts.

The last business before adjournment was the annual election, the following being the principal officers elected: president, Dr. A. Jacobi, New York; vice-president, Dr. William Govan, Stony Point; secretary, Dr. William M. Smith, Maulius; treasurer, Dr. Charles H. Porter, Albany. Dr. S. G. Wolcott, of Utica, was elected delegate to the Massachusetts State Medical Society.

Recent Literature.

Diagnosis and Treatment of Ear Diseases. By ALBERT H. BUCK, M. D., Aural Surgeon to New York Eye and Ear Infirmary; Instructor in Otology in the College of Physicians and Surgeons of New York. New York: Wm. Wood & Co. 8vo, pp. 411.

This constitutes one volume of Wood's Library of Standard Medical Authors, and its aim, as stated in the preface, is "to present, in text-book form, a picture of diseases of the ear as they have appeared to the author in hospital and private practice."

It begins with a sketch of the physiology of the organ of hearing, which gives in a clear and concise form the points important for understanding the pathology of the organ; this is well illustrated, and sufficiently thorough for the purpose intended. Next follows a chapter on the examination of patients, giving the tests for the hearing, and the instruments for and methods of examining; no exception can be taken to the advice here given, which is excellent, although we cannot help feeling it might have been a little more concise.

After this we have the diseases divided as follows: diseases of the auricle, of the external auditory canal, methods of examining the middle ear, diseases of the middle ear (non-purulent forms), of the middle ear (purulent forms), fractures of the temporal bone, diseases of the mastoid, miscellaneous conditions of the drum-membrane, ossicles, and tympanum, aural disease in which the labyrinth is believed to be involved.

All of these subjects are treated in the most interesting and, generally, in the most thorough manner, and some of them, where the disease either from its many varieties or from its seriousness seemed to demand it, are copiously illustrated by cases. This insertion of cases seems to us, in a few places, carried to excess, and to diminish rather than add to the pleasure of reading the book, but in others, as, for instance, in mastoid disease, they are indispensable for rendering the subject clear, and they, at least in this place, do this in a way that would be impossible by simple descriptive text.

For impacted cerumen we are rather surprised to see such strong ground taken in favor of the use of instruments rather than the syringe, and in ordinary hands cannot regard the instruments as so safe as the stream of water. To be sure there is a possibility of conditions behind the obstructing mass which contraindicate syringing, as the author states; but, aside from ignorance of the accurate anatomy in those who are not dealing with the organ daily, there is always the possibility of abnormal curvatures and exostoses which are extremely sensitive. We still believe that preparatory softening and then syringing will better meet the majority of cases than any other method.

The connection of inflammations of the vaso-pharynx with ear disease is well discussed, and the rules for applications to the vaso-pharynx are clear, simple, and good.

The description of acute purulent inflammation of the tympanum is excellent, and the treatment advised judicious and thorough. Chronic otorrhœas are admirably portrayed, and careful attention given to the innumerable varieties which are seen in practice; in this subject, however, we notice one, and the only important, omission in the whole book; more specific directions should have been given in regard to looking after the relapses which are so apt to occur in any case where the drum-membrane has been destroyed; such relapses, if treated immediately—and the patient can generally be told what to do for himself—are readily relieved, but if not so treated are apt to degenerate into a chronic condition, requiring long-continued attention on the part of the surgeon. Every such case should, in our opinion, be warned of this possibility, and instructed accordingly.

In regard to syphilitic ear disease, Buck, while not asserting positively his belief in its existence, inclines to think that there is such a specific trouble. He gives three interesting cases as illustrations, the chief characteristic of which was a melting away of the drum-membrane; but inasmuch as we have seen the same thing occur several times in cases of phthisis and in scrofulous children, we are inclined to think that it may occur in any wasting disease, and that at least that form is not specific.

The relation of life insurance companies to chronic otorrhœas is referred to in a note on page 236, where it is advised that, if the discharge is thin, odorless, unattended by pain in the ear or head, or by pressure anywhere about the ear, the applicant be taken; but if the discharge is abundant, offensive, occasionally bloody, or attended by occasional pain in the ear or side of the head, the risk should be regarded as extra hazardous.

For all inflamed mucous membranes, Buck is a strong believer in the use of nitrate of silver; four hundred and eighty grams to the ounce to the tympanic mucous membrane is, however, unsafe.

We are glad to see the introduction of the term "desquamative inflammation" used in reference to collections of epithelium in the tympanum, but its use could be further extended, as the same thing occurs in the deeper meatus, and Wendt, who first introduced it, considers it due to an inflammation of a thin membrane covering the bone.

In speaking of the artificial drum-membrane no mention is made of Yearsley's cotton, which we believe is the most useful of any of the forms, when any can be used.

The most thoroughly original part of the book is that upon fractures of the temporal bone, which should form the basis for further investigations.

On page 359 we find the term emissary mastoid veins applied to the veins and foramina leading from the mastoid cells, which is entirely incorrect, as the term has a strict anatomical meaning,¹ and can only be used for the large connection between the lateral sinus and the superficial tissues on the side of the neck, and the same mistake is made in another place in speaking of phlebitis of this vein, and a misquotation of another author is consequently made.

The whole book is eminently practical, the treatment advised is judicious and efficient, with the two exceptions we have pointed out; it is almost entirely a record of individual experience, but contains many original practical points in diagnosis and treatment. We can most heartily commend it.

John Hunter and his Pupils. By S. D. Gross, M. D., LL.D., D. C. L. Oxon., LL. D. Cantab. Philadelphia: Presley Blakiston. 1881. 8vo. pp. 166.

The JOURNAL has already shown its appreciation of this tribute to the "founder of scientific surgery" by the imperfect abstract of advance sheets to which the courtesy of the publishers has allowed it to treat its readers. The book itself does not disappoint the high anticipations raised by the foretaste.

It is refreshing to read the story of a life so fully devoted to science, and the reader will readily appreciate Professor Gross's enthusiasm for his subject, which led him to extend what was originally intended for an essay to its present size.

One cannot help feeling that Hunter, like Milton, must have been an exceedingly disagreeable man to live with; at the same time he had the faculty of inspiring singular affection on the part of certain pupils; something of the same charm hangs about the record of his life, and one forgives his ill-temper, his bad manners, and his coarse expressions, as did Abernethy and Cooper and Pylsiek, in admiration for his devotion to science and his love for truth.

A noticeable feature of the essay is the fact that it presents Hunter surrounded by the other medical men of his day. The reader not only sees Hunter as an individual, but acquires a knowledge of the state of medicine and of the medical men of the time, while the sketches of his pupils show the continuation of his influence upon scientific medicine years after his death, in America as well as in England.

Possibly some of Hunter's letters might have been given with advantage; part of the Jenner correspondence would have shown the devoted scientist and the affectionate friend, and illustrated his singular lack of education; still we must confess the letters would have added little, since they contain little of value, and are scarcely more than a catalogue of Hunter's wants joined with expressions of regard.

The phototype of Sharp's well-known engraving of Sir Joshua Reynolds's portrait is an excellent reproduction, and forms a fitting and handsome frontispiece.

The volume will prove an ornament to the study table, where it will be a constant incentive to whatever is best and noblest in a noble profession.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 17, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Remittances by mail should be sent by money-order, draft, or registered letter to
HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

TRAVERS VERSUS BOARDMAN: AN ACTION OF TORT, AND WHAT IT TEACHES.

AN action for damages was tried last week before the superior court of this county, wherein the defendant was a well-known and reputable physician of Boston. The medical elements involved in the suit are so peculiar that we believe a summary of the case will be instructive to our readers. The material facts brought to light at the trial were as follows: In the autumn of 1878, a woman, the plaintiff in this case, applied at the Boston City Hospital for treatment for some uterine disease; she was referred to Dr. W. E. Boardman, the regular physician on duty in the department for such patients. In the course of the treatment, which extended through more than two months, Dr. Boardman, in the presence and with the assistance of Dr. Wyman, the medical externe, performed on one occasion the simple operation of puncturing the cervix for local depletion, the knife being used, of course, with a vaginal speculum in position. This was the only operation to which the patient was ever subjected at Dr. Boardman's hands. The case was dismissed as convalescent before Christmas; and at that time the woman testified her appreciation of the services rendered by urging Dr. Boardman to accept some tokens of her regard. The next that was heard of the case was about three weeks later, when the patient re-appeared, charging Dr. Boardman with malpractice, and insisting that he should "do something for her." This was a premonitory symptom of her present "complaint," which, as presented by her, under oath, in court, before a crowd of men, is in effect as follows: She alleges that at her fourth and last visit to the hospital, Dr. Boardman, with Dr. Wyman's assistance, placed her in position on a table, and then, without her permission, and, as she believes, for experimental purposes only, amputated her clitoris and with it excised a piece of the mucous membrane of her vulva "as large as her hand;" that she bled freely after this operation; that she knows the parts removed to have been as she describes, for she saw them in a basin where the doctors placed them; that as soon as the operation was finished she arose from the table and went home; that in consequence of that operation she has been in mental and physical misery most of the time in the interval since; her menstruation has stopped; she has spasmodic pains; she has lost many pounds in weight; she is disabled for her ordinary work; she has distressing hallucinations; and she has been obliged to break an engage-

ment of marriage because, with the loss of her clitoris, she has found on trial that her sexual desire has departed; that she knows her clitoris is gone, for she has examined her person with the aid of a mirror. For this loss, and for its direct and indirect consequences, she claims damages from Dr. Boardman to the amount of \$3,000.00. Her allegations as to the mutilation of her vulva were supported at the trial by the testimony of one of her neighbors, a spinster, who examined the Travers' genitals soon after the alleged operation, and found "a piece of the clitoris gone"; also by the testimony of two men (who are unknown to fame or to the regular profession, but who, because they write "Dr." before their names are by that mark as good as the best in a court of law), one of whom swore that he was of the opinion that the clitoris had been amputated, for he had examined the woman more than a year after the alleged malpractice, and had observed a linear scar at the place where the clitoris ought to be. The cross-examination of these foreign gentlemen was extremely racy. The only other inspection to which, so far as the testimony showed, the woman had submitted herself was on one occasion when Dr. J. A. Lamson, a regular physician, examined her in company with another well-known practitioner; both agreed that they found no defect or loss of tissue whatever about the genitals, the spot indicated by the plaintiff as the scar of the operation being the meatus urinarius and readily admitting a female catheter. Such are the essential facts of this case.

Considerable medical expert testimony of excellent character was introduced for the defense; but we cannot dwell upon it. Dr. Boardman, while denying unequivocally that he had in any way operated upon the plaintiff's clitoris, admitted, with the experts, that, assuming the operation to have been done as stated by the woman, such an operation would be an unjustifiable mutilation, and rightly described as malpractice, an ingenuous indication of the complete trustworthiness of his defense. It was pointed out also by the experts that with the vaginal speculum (Higbee's pattern) in position, such an operation as was alleged by the woman to have been done at that time was impracticable, and that it would have been physically improbable that she could leave the operating-table and go home at once after so much mutilation; moreover, that the remote effects which she described, especially the suppression of the catamenia, were not such as would follow amputation of the clitoris.

We regret that we have not the space for an extended abstract of the honorable Judge Putnam's charge to the jury. It contained but few morsels of encouragement for the audacious plaintiff. He said distinctly that for the jury the question was one mainly of veracity; if the jury had any doubt of the woman's story, for upon her rested the burden of proof, then they must bring a verdict for the defendant. To assist the jury to understand the full bearings of the case, his honor stated very clearly the principles of law involved; that in a physician's dealings with his patient there is an implied contract, as distinguished from a written or expressed contract; that in discharging this

contract, a physician must possess a reasonable degree of that skill, learning, and experience ordinarily possessed by physicians living at the time; that in the exercise of this skill, learning, and experience, he needs to use ordinary care; and that as regards liability it makes no difference whether or not the service rendered was gratuitous.

The jury deliberated many hours on the simple question of veracity before them, and at length reported that they were unable to agree; it was stated on good authority that they were equally divided.

Now, this case suggests many reflections; we can mention two or three only of the comments that occur to us. In the first place, this trial illustrates the deplorable facility with which such actions may be brought, and the outrageous advantage which designing persons have in bedaubing honorable physicians with the slime of innuendo and suspicion. The nastiest strumpet in the town has it in her power thus to annoy the best and noblest man among us. In dispensary and hospital practice, as well as in the privacy of office work, the physician of highest skill and purest motives may fall afoul of one of these harpies, may unsuspectingly do the simplest operation for her relief, and a few months later may find himself in court, a defendant in a suit wherein he is accused of doing things which he never did or dreamed of doing, the doing of which, indeed, would stamp him as a fool or a knave. Until some right of supervision is exercised by judges so that such fraudulent suits are prevented from obtaining a place on the docket, or until the law requires that all costs, including the defendant's counsel fees, shall be paid by the plaintiff if he loses his cause, these miserable actions of tort will be springing up, smirching the reputations of honorable men and displaying their names in the daily press in such a manner as to mislead the public into a feeling akin to a belief that the accusation is more than half true.

Then what shall we say of the "trial by jury"? In this case six men believed the utterly improbable story of this female Thersites, who babbled her filthy yarn with indecent freedom and was able, by her vile allegations, to neutralize in their minds all that could be brought to contradict her or to show the inherent improbability of her nasty narrative. Such a phenomenon is not reassuring to honest suitors, and does not inspire reverence for this ancient method of administering justice.

Of the conduct and character of so-called professional men, whether lawyers or physicians, who lend themselves to promote the prosecution of such actions at law as the present, of their motives, their behavior in court, their expectation of reward, we forbear to make extended criticism; we have an opinion which if expressed might not be considered complimentary to those privy counsellors.

Finally, the present case is an illustration, for the thousandth time, of the need of a change in the methods of using medical experts. If, before the trial, any one of the able physicians there present had been agreed upon by both parties, or, in default of such agreement, had been appointed by the court, to present and inter-

pret the medical data of the case, including proper notes of the plaintiff's present physical and mental condition, the sneer of her counsel that "the doctors all hang together, of course they do; that's to be expected," would not have been heard; indeed the case would probably have been taken from the jury. When the choice and testimony of medical experts in civil and criminal suits rests by authority on some more substantial foundation than mere partisan expediency and availability, we shall not be obliged to read in the newspapers, between the lines of the court calendar, that the jury in a given case were unable to agree, because half of them considered a scheming woman and two irregular practitioners more trustworthy than six of the best-known among the regular physicians of Boston.

We hope that Dr. Boardman will insist on a new trial before another jury, for the matter ought not to rest in its present undecided state. He is sure of the sympathetic support of the administration and medical staff of the City Hospital; indeed, he may regard the entire profession as his allies, in a matter touching so intimately the common interest.

SMALL-POX AND REVACCINATION.

By an excusable oversight we were led to make an incorrect statement in our editorial on this subject in last week's JOURNAL. We there stated that vaccination as administered by our local boards of health, as a compulsory measure, was legally limited to the ages below the period of school attendance, and that revaccination was a purely voluntary means of prevention which grown-up persons might adopt or neglect as they saw fit. This is, however, not quite accurate. Our statement was based on section 27 of chapter 26 of the General Statutes of Massachusetts, and we overlooked the very next section, which indirectly gives the local boards of health the authority to compel the revaccination of all the inhabitants whenever, in their opinion, the public health requires it, excepting only such of the inhabitants as can prove to the satisfaction of these boards of health that they have been successfully vaccinated or revaccinated within five years.

The Boston Board of Health recognize fully the great advantages of revaccination as a powerful agency in the prevention of an epidemic of this dreaded disease; but they do not feel that as yet the public health has required any official action on their part looking to an enforcement of the authority vested in them by the general statutes. They rely on the medical profession to use every effort to secure the vaccination or revaccination of that portion of the population who are in need of it, and who are likely to apply to physicians for advice. This cooperation of the physicians with the sanitary authorities will be of the first importance. There will then only be left the unwilling and indigent for the exercise of the arbitrary powers for their protection invested in the Board of Health. These, we are assured, will be brought to bear in due time. The subject was discussed in the Board

of Health more than two months ago, but, for good reasons, action was deferred for a time. Meanwhile, there is no emergency; but should such arise, either in the city or at quarantine, the health authorities are amply equipped and ready for the prevention or suppression of any epidemic of small-pox which might arise. The Small-pox Hospital can within twenty-four hours receive and accommodate sixty patients. Every physician is obliged to report immediately the existence of any case, and the board are prepared to remove at once such a patient, and to take prompt measures to prevent any spread of the disease. There has been but one death from small-pox in Boston during the last three years, and there is at present no case either in the city or at quarantine.

Meanwhile, the Boston Board of Health looks to the medical profession to see to it that their patients are properly vaccinated or revaccinated whenever such steps seem for any reasons to be called for, and the community can rest assured that the board on its part is ready to take prompt measures for the public safety whenever occasion shall demand such.

AN ANTISEPTIC REPLY TO "DRESSER."

In the last issue of the JOURNAL there appeared some criticisms upon our editorial remarks of January 27th, on the spray in antiseptic surgery. These criticisms were over the signature "Dresser," a signature possibly indicative of the writer's past or present hospital experience, possibly of his manner of serving up the JOURNAL; however that may be they were certainly sufficiently solemn and serious. The writer laments our want of *chauvinism*—we apologize for going outside of Webster for our words—in the field of science, where he apparently considers this quality even more desirable than in politics or letters. He also regrets what he is pleased to term the superficial character of our remarks, having, it seems, prepared himself for the perusal of an exhaustive, if not final, treatise,—an indirect compliment to the average editorial of the JOURNAL, which is duly appreciated. "Dresser," who also seeks his words abroad, thinks, moreover, that if unable to stimulate faith the JOURNAL should at least be careful in its "*résumé* of facts." Although confessing that very little is as yet known as to the action of the spray, our critic may himself be fortunate or bigoted enough to have reached the highland of unquestioning belief in antiseptics in general and of the spray in particular, and be content to be there without knowing why; but some concession is due to those less well satisfied, doubting Thomases, to whom he refers, and who are still hesitating whether or not to carbolicize their fingers. Anything which will help honest beliefs or unbeliefs, or which contributes to the elucidation of disputed subjects, it is the duty of a journal to bring, as far as may be, to the attention of its readers, never forgetting that many of them are capable of reaching their own conclusions as to the value of these contributions. Dis-

cretion and authority should temper but not strangle enterprise.

The Louisville *Medical News*, referring to our mention of Von Brun's "Fort mit dem spray,"—which it renders "No more of this nebulous myth,"—stigmatizes us as believers in the theory and practice of Lister; Dresser, on the other hand, is disappointed that we do not "stimulate such faith." It is evident that neutral ground is unsafe where a question is concerned so vexed and so exciting as the value of antiseptic spray in surgical operations.

The articles of Von Bruns and Mikulicz are worthy of note as recent foreign contributions to a subject likely to be more and more actively discussed. They merely show the tendency of theory and practice in other medical centres. Mikulicz's experiments have, it is true, much the appearance of being made to order or to support a previously assumed position, but they deserve attention from the writer's propinquity to so distinguished a surgeon as Billroth.

If it can be satisfactorily *proved* that the spray or any other part or the whole of antiseptic surgery as practiced by Lister is unnecessary, so much the better; it should not, however, be done in a spirit of boyish and jubilant triumph over a man deserving so much of humanity and of the profession.

Dislocated hips were unquestionably reduced here and there by manipulation before Professor Bigelow's work on The Hip was issued, but the process was not popularized nor explained on a sound mechanical and anatomical basis. Before Lister there was *no* methodical antiseptic surgery as such. Let this fact be *always* and *forever* acknowledged.

Lister's present methods may be modified or superseded, but the impulse which he has given to antiseptic surgery, the hopeful aspiration after better results which he has created, will survive.

The excellent contributions of our home workers towards a true appreciation of the value of antiseptics were not quoted by us, these being well known to, and easily within the reach of, most of our readers. Those interested in this controversy over antiseptics who have not already acquainted themselves with these contributions, and we imagine the number must be very small, will do well to look up a paper,¹ by Dr. A. T. Cabot, giving a statement of experiments on the strength of antiseptics, as well as an article² by Dr. Stimson on the value of the carbolic spray as a preventive of putrefaction, and the reply³ to the same by Dr. Watson.

All three of these papers are worth study, and it was not so much with the object of stimulating either faith or skepticism as with the desire of inciting to more of just such work that we called our readers' attention to this subject. Any of our countrymen who may succeed in accurately determining the real value and exact results of antiseptic procedures in operative surgery will not fail of an appreciative recognition.

MEDICAL NOTES.

—The newly-elected president of the London Clinical Society, Mr. Lister, on taking the chair for the first time, will deliver an introductory address on the Catgut Ligature, and a discussion will probably follow.

—At Bedford, England, last week, no less than forty anti-vaccinators were brought up at the Borough Police Court, charged with neglecting to have their children vaccinated. The offense was in no instance denied, and the defense simply "conscientious objection." Most of the defendants had been previously convicted of a similar breach of the law. The bench, notwithstanding, only imposed a fine of six pence, remitting the costs entirely. A like amount was ordered to be paid by those whose children had not been vaccinated before they were three months old, while, in other cases, orders were made for the operation to be performed within three months.

—The table of suicides for the city of New York for the year 1880, prepared by Dr. Nagle, register of vital statistics, shows that the total number was 152, of whom 121 were males, and only 31 females; 74 were married, 34 single, and twelve widowed. Germans were in the majority, reaching 64. United States, 35; Ireland, 20; France, Poland, Scotland, and Italy, 3 each; England, 5; the balance, of other countries. The means of self-destruction employed were: shooting, 39; drowning, 14; hanging, 28; cutting, 20; leaps from heights, 9; gas, 2; poison, 40.

—The opposition to the confirmation of Dr. C. F. Folsom's nomination to the National Board of Health, which, as far as we can learn, originated with a member of the Massachusetts delegation to the national House of Representatives, will certainly not meet with the approval of the profession in the State of Massachusetts.

NEW YORK.

—Since the first of January slightly over one hundred cases of small-pox have been reported. The most of these have occurred among the Italians and negroes in the lower part of the city; but even Fifth and Madison Avenues have not been without a small proportion of cases. In the month of January the health officers vaccinated 6,471 persons free of charge, and from fifty to a hundred individuals now present themselves for vaccination each day at the Health Department. Many physicians in the city get their vaccine virus from the Vaccination Bureau, which also supplies all the public hospitals, dispensaries, and other charitable institutions, and is constantly in receipt of orders from all part of the country. The farm where the virus is obtained is one of thirty acres situated near Clifton, New Jersey, on the Erie railroad. The department is at present using from ten to twelve calves a week for the purpose. The reconstructed small-pox hospital on North Brothers' Island is now fitted up for the accommodation of about forty patients, and it is the desire of the Health Commissioners to relinquish the Riverside Hospital on Blackwell's Island entirely, if an

appropriation can be obtained to put up the requisite additional buildings in the former location, and to purchase a suitable boat for the transfer of patients.

A record of the city's mortality during the past year, arranged by streets, has just been completed in the Bureau of Vital Statistics, under the direction of Commissioner Janeway. The largest number of deaths in any one street occurred in First Avenue, namely, 681; of which 620 were in tenement-houses, and 392 among young children.

—The committee of the "Hospital Saturday and Sunday Association," appointed to make a distribution of the moneys collected during the last week of 1880, met in the Mayor's office on February 10th, when it was announced that the total amount collected was \$36,199.56, of which \$15,199.56 had been specially designated by the donors, while the remainder was to be appropriated to the general fund.

—At the stated meeting of the Academy of Medicine, held February 3d, Dr. William T. Lusk exhibited a specimens of uterine hydatids, with explanatory remarks, and the president, Dr. Fordyce Barker, delivered his second inaugural address, which was characterized by his usual elegance of diction. In the course of it he congratulated the academy on the substantial progress which it had recently made in its various departments, and spoke of the important relations and responsibilities which it bore to the profession and the community at large. Congratulatory remarks were also made by Dr. Beverley Cole, of San Francisco, and by Drs. Willard Parker, Austin Flint, S. S. Purple, James Anderson, and Frank Hamilton, of New York; after which the Fellows of the Academy and their guests repaired to the dining-room, where the "loving cup" was passed around and a collation was partaken of.

The annual meeting of the Committee on Books and Papers of the State Charities Aid Association was held the last week in January, and the large attendance on this occasion showed the public interest that is felt in the work of the committee, which was organized February 1, 1874, at the suggestion of Mrs. Alfred Pell. The annual report stated that during the year 1880 a daily average of four hundred papers had been collected from the boxes in railway-stations, ferry houses, and other public places, and these had been sent, as heretofore, to the large hospitals and other charitable institutions. Of course, many of the inmates did not read at all, but since an effort had been made to cultivate this taste it was learned from the chaplain of Blackwell's Island that whereas formerly only about fifteen books were taken out of the library then in the course of a week, the average was now one hundred a week. During the past seven years packages of reading-matter had been sent to one hundred and thirty-five different institutions. Mr. William E. Dodge, who presided at the meeting, made a few remarks, in which he stated that he thought the report of the committee was a model one, giving, as it did, a complete story of this quiet, beautiful charity. An ordinary man, he thought, could hardly understand the tedium of hospital life, and the committee had

done much to help those who had to endure this. Many of the patients in the hospitals, and especially those in the surgical wards, were well enough to read, and the papers and books which are furnished through this agency were of inestimable value to them. Addresses were also made by Messrs. Willett, Philip Schuyler, and others.

— At the last meeting of the Medico-Legal Society, February 2d, Dr. E. C. Harwood exhibited a section from the cervical vertebrae of a woman who had attempted to commit suicide by shooting herself in the mouth. The ball lodged in the bone, as was discovered after her death, six weeks later, and remained as evidence of the attempted suicide, which the woman had endeavored to conceal. The legal bearing of the case, he said, was in relation to its connection with the coroner's office, which had made no investigation of it, since the certificate of death did not indicate that an attempt at suicide had been made.

Miscellany.

REVACCINATION.

MR. EDITOR.— Hoping, as we all must, that the small-pox epidemic with which you threaten us may visit us lightly, I, for one, wish we might be spared one of the most disagreeable companions of an epidemic which, however, has already reached us. I refer to dogmatic statements concerning either prevention or cure, which rest on no more certain basis than the hobbies of their author. Forgive me if I allude to your editorial of February 10th.

Your tables of ages are interesting; and I quite agree with you that they show the necessity of vaccination and also of revaccination at from fifteen to twenty years of age; but where in the world do you find your authority for the statement that revaccination is a "measure universally recognized as necessary after intervals of eight or ten years from the most recent successful vaccination"? Now, of course, you did not mean to say that this was *universally* recognized. Hobby must have taken the bit between its teeth for a moment. Nothing is universally recognized about anything that I know of, least of all epidemic diseases, unless it can be that they are nasty things. But why do you think that it is recognized at all? What statistics have you in support of it? Because the effect of the first vaccination is greatly weakened during the years of rapid growth does it follow that a revaccination in adult life does not give a more permanent immunity? You seemed filled with holy horror at the ignorance and inertness of those who do not share your apprehension. It seems to me from your quotation from the *Lancet* that that excellent journal has also bestridden its hobby. How does it know that an effective revaccination is a better protection than small-pox itself? Certainly some have the disease more than once, certainly vaccination is not always a protection; but why so precise a statement? As I have said above, I admit the advisability of revaccination in early life, and I should advise it again to any one directly exposed or likely to be so; but let us remember that we have a large and increasing class of the idle and nervous who, for want of better employment, distress themselves about infection and contagion. They do harm to them-

selves and harm to others, and the fire of their hyperaesthesia is fed by dogmatism such as I have referred to. Now it seems to me that such positive statements should be made only on positive evidence.

DELTOID.

LETTER FROM WASHINGTON.

MR. EDITOR: As we do not like to be outdone by our English brethren, the medical profession here have recently issued a very lively second edition of the *Guys Hospital* experience, which is worthy of note. It is already known to the readers of your journal that a movement has been on foot for some time past to establish a general hospital without regard to age, sex, color, previous condition or sectarian influences. To do this Congress has to render assistance, and as we are nobody's constituents nobody cares to help us along, unless, in our capacities as doctors, we can bully sick Congressmen, or have the means to dine and wine them into complaisance for the sake of good fellowship. But, emboldened by the prospect, slim as it is, of the establishment of such a suitable hospital, some of our long-suffering brethren in attendance upon Providence Hospital, in this city, joined their efforts to the movement, and may have been a little indiscreet in their expression of opinion as to the condition of things now, and for a long time past, existing in said Providence Hospital. For this, and other reasons, the head of the institution, Sister Beatrice, a sister of charity, requested the resignation of those who were the most outspoken, which they were obliged to present, and their colleagues went with them without hesitation, but not without exception, as two of the staff still remain, and they both represent the older practitioners of the District, and have Catholic interests at stake; how far this may influence their action in the matter is of course not for me to say. Dr. Johnson Eliot, as one, in remaining continues to represent the interests of the medical department of Georgetown University, he being a clinical professor of that college. Dr. Eliot was chairman of an important committee to further the scheme for a new hospital, bring it before Congress, etc.

Our daily papers have for some time past been filled with statements, interviews, etc., from both parties, and the profession was curious to know who would fill the places of the deposed medical board. Of course there were medical men ready and willing for the asking, and some guessed quite correctly in advance a fair proportion of those appointed; which appointments were not made until there had been a full and free expression of opinion on both sides. The old staff represented very satisfactorily our two medical colleges and the general profession. The new staff contains but one college man (with the exception of Dr. Eliot holding over). Dr. Robert Reyburn, a lecturer in the medical department of Howard University, which institution was originally for the benefit of the colored race, but is now thrown open to all, male and female, white and black, with a fee of \$80 for all the expenses incurred in a three years' course. Dr. Reyburn was formerly in charge of the Freedman's Hospital, and a professor of the same college where he now is, was afterwards in the Georgetown University Medical Department as professor of surgery, then as professor of anatomy; on the reorganization, a few years ago, of

that college faculty, a complete change was made, and his professorship was vacated. Three of the new staff are also connected with the Columbia Hospital for women. They were appointed some time since to fill the places of a staff which had seen fit to resign in a body, on account of what they considered objectionable features in the hospital management; this occurrence has already been fully alluded to in previous pages of this journal.

Our first intimation of the trouble that was a-brewing came in the shape of a public appeal made to the President of the United States, and signed by James Rea and others, including several clergymen, dated December 28, 1880. It was to the effect that the existing contract between the sisters in charge of the hospital and the surgeon-general of the United States army, which was to provide for seventy-five beds for Government patients, at \$15,000 a year, should be annulled by thirty days' notice, and no new contract made with this or any other *sectarian* institution. It further states as reasons for such a request, that this contract was abused, and was in a certain sense a fraud, and then complained of abuses in the personal management of the hospital, in that the prescriptions were compounded by sisters of whose pharmaceutical attainments the physicians had no knowledge, and that sometimes the medicines as given were found to be very different from the medicines as ordered, and not suitable to the purpose. That no physicians or visitors were allowed in the house after 8 P. M., and they, the physicians, were not called in attendance through the night. In consequence of the harsh and inhuman enforcement of these rules fatal results sometimes followed.

This was a very severe arraignment, and, as subsequent events gave color to a suspicion that some of the medical men in attendance may have furnished material for such an appeal, Dr. Rea published a statement that none of the information which upon the appeal was based had been supplied by the doctors. It may be well, also, to state here that the physicians have always had access through the night to the patients in the hospital.

The appeal was very properly referred by the President to Surgeon-General Barnes, who furnished his reply almost immediately, first stating that the mode of admission of these patients, as far as his office was concerned, was conducted in a proper, business-like manner. Then he compliments the hospital as follows: "*The medical staff of the hospital is most excellent, including some of the leading members of the profession.*" "The institution was created by the religious order having charge of it, and will compare favorably with similar *sectarian* hospitals. Its rules are no more stringent, its medical attendance and nursing no less excellent, and its good results as great." "Frequently the number of free patients borne on the Government roll is in excess of the number appropriated for, and it is but just to the management of this institution to say that under all circumstances they have cheerfully exerted themselves to meet the necessities of the poor and suffering."

He points out that there are no other hospitals suitable for transient paupers, and that to annul the existing contract without some other provision would be to inflict much suffering, especially at this season.

The tone of this letter is as if written by one who was confident that so far as the workings of his office

was concerned, the contract with the hospital was perfectly correct and proper in its object and mode of execution. That so far as the hospital was concerned, having such confidence in the medical staff, which he expresses in strong terms, if there was fraud or mismanagement in that direction he would have received some decided intimation from them; and that not having this he feels warranted in his expressions of opinion. Notice that he compares it favorably with similar *sectarian* hospitals, as if in his mind there was a distinction, but that he does not wish to be biased by any sectarian prejudices *against* the hospital. It is but fair to presume that, taking everything into consideration, if that letter were to be written over again, its contents would be of a very different nature.

With the publication of this letter from Dr. Barnes is a statement from the sister in charge that the mode of admission is regular, vouchers all right, etc.; that religious views are not interfered with, and that the reason there is no resident physician is because of the telephonic communication. But the telephone has only been in use in the hospital for a few weeks, and this objection has held good for years. That the sister who compounds the medicines is a thoroughly competent pharmacist, and her ability is vouched for by those *competent* to examine into that question; and, finally, that the physicians have all the authority they may desire, and no interference with their directions regarding a patient is permitted.

Just here a serious mistake was committed by the staff giving their tacit agreement to this letter and statement, as, armed with the letter for a shield against further objections, the sister in charge demanded forthwith the resignations of some of the staff. Again, they made a mistake by yielding to the solicitations of the senior member of staff, putting the matter in his hands, and allowing a week to pass by in the hope of adjusting the difficulty, instead of coming out positively, with no compromise, and declaring the existing state of things. But it was of no avail; they had to go, and their fellows went with them.

In their resolutions, signed upon resigning, they state that the Congressional act of incorporation of the hospital confers no authority whatever upon the medical board, either in the general management of the hospital or in the treatment of the patients, and that the members of the medical board have found it impossible to enforce or obtain enforcement of their necessary regulations for the hospital or its sick. This was signed by Drs. King, Ford, Howard, Beale, Lincoln, Thompson, Charles E. Wagner, and Prentiss; subsequently, Drs. Loring, Richez, and Burnett resigned as consulting ophthalmologists and aurists; Dr. Trott as clinical clerk, and Dr. D. R. Wagner is reported to have resigned; but no public statement to that effect has appeared over his name, and his name stands second upon the list of the new staff, which is as follows: Drs. Tyler, D. R. Wagner, Newman, Bulkley, McKim, Roberts, Stanton, J. T. Young, Bayne, Eliot, and Reyburn.

It is not necessary, and it would only take up space, to attempt to give in detail the published opinions of the individual members of the medical board, save in one or two special points, as they all concur in adding force to the resolutions as adopted. Dr. J. Ford Thompson laid the blame mainly upon the sister in charge; that his experience with the hospital previous to her assuming control — and he has been with the

institution from its beginning — was that of a harmony which enabled all to work for the common object.

Dr. N. S. Lincoln stated that the sisters did not wish the medical board to have the privilege of choosing their associates; that it was necessary at one time, when a number of cases of erysipelas were in the wards, to threaten an investigation on the part of the health officer, so as to enforce the necessary precautions for preventing the spread of the disease; that certain hours were set apart, three times daily, for the administration of medicines, which were not to be deviated from; and cases suffered accordingly. He cited one case where a patient was left to suffer in agony, while the sister completed her prayers before giving an anodyne. That the sister who acts as the pharmacist can only put up the simplest kind of medicines, and that the sister in charge emphatically refused to allow respectable young graduates to remain in the hospital over night, while old debauchees have spent three months at a time there. He said the building was built by the United States Government from an appropriation by Congress of \$30,000. This sum might be materially increased in amount by taking into consideration other and subsequent appropriations.

Dr. A. F. A. King stated that there were no diet lists; that but few instruments were purchased, however inexpensive; that, notwithstanding the sisters had recently purchased real estate mounting up in cost into the thousands, there was no money for such purposes, — not even a microscope in the hospital, — and that it was customary for the sisters to give chloral hydrate, liquor, etc., to cases of delirium tremens, at their own discretion. He cited a case of delirium tremens where he had positively and repeatedly interdicted the use of liquor, and at two several visits found his patient under its influence. Remonstrance was of no avail; for the sister in attendance thought it best to give it, and a report to the sister in charge only resulted in her sustaining the sister in attendance. Dr. King further said there had been no post mortems held in the institution for three years past.

This would seem to be enough, if not too much, for a letter on local matters, were it not that the institution is dependent mainly upon the Government for its support, and that it is the money of the people of the United States which is contributing to it. Further, it is the only institution here which patients from other cities, accustomed to the benefits of proper hospitals, can make use of in case of accidents or prolonged sickness.

A full and thorough investigation, as ordered by Congress, ought to follow such statements as these, if any more money is to be appropriated by Government to this hospital.

A new phase has recently developed, which may give a political complexion to this state of affairs; but, if so, it will be undeserved. A few students attended the usual Sunday morning clinic, and found two colored students from Howard University in attendance; whereupon the majority of them left the hospital. This was entirely a personal matter. The medical board have made no distinctions of this sort. Howard University students, male, female, and colored, have been in attendance upon the clinics without any interference. The class lists of both colleges each year show a fair proportion of New England students, and this question of color has never crept into the colleges as yet. W. L.

February, 1881.

PROFESSOR GAIRDNER ON POINTSMEN'S WORK.

IN connection with our recent remarks upon defects of vision in railroad employees, we are led to call attention to the *Lancet's* notice of a case of passing insensibility in a pointsman on a Scotch railway, whose duties entailed serious and prolonged strain upon the nervous system, as showing that defects of vision form but one class of dangers to be guarded against.

Professor Gairdner, of Glasgow, moved by recent railway accidents due to faults of pointsmen, publishes a letter in a Glasgow contemporary, in which he details the case which he had treated in the Royal Infirmary in 1872. This patient was a pointsman at Rutherglen station, where from 250 to 300 trains were due every twenty-four hours, or about one train, on an average, every five minutes. Though the intervals at night were long, in the daytime they were such that, in the man's own words, "trains would pass for an hour together as close as they could follow." The work was divided into a day and a night shift, the latter being thirteen hours, the former eleven. The pay was £1 a week. There was no time for meals, which had to be taken while at work. The wonder would be how any man so situated could escape giddiness or some break-down in the nervous system. The fact that men do so, so often, is a wonderful testimony to the principles on which the nervous system is constructed. But, as it happened, this man came to suffer from a nervous complaint characterized by passing insensibility, of which the patient was sometimes quite unconscious. The man said that when his duty was most anxious the disorder was at the worst. Dr. Gairdner thinks the public are to be congratulated on that man having come under treatment. It seems highly probable that in this way an accident was averted. Since then Dr. Gairdner has taken pains to ascertain the rules of French lines, and finds them much more considerate of the limitations of human faculty. On the Scotch line the hours have been reduced to eight, but without special intervals for taking food. The patient got well after two or three months' hospital rest and treatment. Dr. Gairdner sets a good example in publishing this case. By itself it shows the need for more consideration of responsible railway servants. If any of our readers have similar cases in their clinical books they will do well to publish them. It must especially be remembered that in the worst attack in the hospital the patient had no memory of what had occurred.

A CURIOUS FACT IN ANIMAL REPRODUCTION.

WITH some comments of its own the following curious freak in parturition, extracted from the *Journal de Médecine Vétérinaire de Lyons*, is given by the *Lancet*.

A curious fact has recently occurred which throws some light on similar cases reported of the human species, but which have been received with considerable doubt by some authorities. Last April, on a farm in the department of Isère, a mare about ten years old gave birth, at full time, to a foal. Soon after the throes of parturition recommenced, and with assistance another foal was brought into the world. Twin foals are sufficiently rare to cause astonishment at any time, but the astonishment of the attendants was changed

into amazement when they discovered that it was not a horse foal they had taken from the mare, but an unmistakable mule. The little creature, unfortunately, and as is generally the case with twins in solipeds, did not long survive its birth. The veterinary surgeon who was subsequently called in made inquiry into the case, and as a result he gives the following explanation: It is a very common practice in Dauphiné to present the mare, when in œstrum, twice to the stallion, and at a brief interval, believing that fecundation is more certain by this procedure. But, as it seldom happens that the villagers can obtain the services of a stallion which can serve the mare twice with only a few minutes between, or yet a second stallion, and as male asses are by no means scarce, they oftentimes employ one of the latter to succeed the horse. And this is what happened with the mare alluded to.

The case is not absolutely unique, even in equine physiology, however, for Fleming, in his Text-book of Veterinary Obstetrics (p. 152), gives six similar instances, and one in which a mare, put first to an English stallion and soon after to a Barb, produced twin

foals—ono resembling the first, the other the second stallion. It may be noted that, of all the domestic animals, the mare is the least disposed to multiparity.

SUDDEN ILLNESS AMONGST THE POOR, AND MEDICAL ATTENDANCE.

THERE is a very comfortable doctrine abroad that doctors are at everybody's service in an emergency, and that they are bound to rise from their beds and go to a distant alley to save a life or ease a pain, without the least prospect of recompense. But why is such mercy to be shown only by doctors? Why does not the public share with doctors the cost and the credit of such service? It is society's duty, not that of any single profession, to see that no human creature, however poor, dies without medical aid. A country like this should make provision for the emergencies of its poor, and not throw the whole onus on the much enduring and little paid members of our profession. — *Lancet*.

Deaths reported 2759; 982 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 548, consumption 441, lung diseases 383, diphtheria and croup 221, scarlet fever 110, small-pox 64, diarrheal diseases

37, typhoid fever 28, malarial fevers 21, erysipelas 20, cerebro-spinal meningitis 19, whooping-cough 17, measles 11. In addition, Chicago reports deaths under five years 93, from "zymotic" diseases 56, lung diseases 32, diphtheria and croup 28, consumption 25, scarlet fever seven, small-pox six, cerebro-spi-

nal meningitis five, malarial fevers four, erysipelas three, typhoid fever two, diarrheal diseases one; total deaths not given. From *diarrheal diseases*, New York 22, Brooklyn and District of Columbia four, Philadelphia and Boston two, New Orleans, Pittsburgh, and Buffalo one. From *typhoid fever*, Philadelphia nine, Worcester three, New York, Brooklyn, Baltimore, Cincinnati, Pittsburgh, and Fall River two, New Orleans, District of Columbia, Lowell, and Clinton one. From *malarial fevers*, New York six, Brooklyn four, New Orleans three, District of Columbia and Pittsburgh two, St. Louis, Boston, Buffalo, and Cambridge one. From *erysipelas*, New York nine, St. Louis, Baltimore, and Cincinnati two, Boston, District of Columbia, Providence, New Haven, and Worcester one. From *cerebro-spinal meningitis*, New York six, St. Louis three, New Orleans and Milwaukee two, Philadelphia, Baltimore, Worcester, Lawrence, Holyoke, and Haverhill one. From *whooping-cough*, New York and Baltimore four, Philadelphia three, Pittsburg two, Brooklyn, St. Louis, Cincinnati, and Salem one. From *measles*, New York five, Boston two, Brooklyn, Pittsburgh, Nashville, and Newton one.

Nine cases of small-pox were reported in Brooklyn; six in Chicago: one in St. Louis; diphtheria 38, scarlet fever eight, in Boston; small-pox five, in Pittsburgh; scarlet fever 36, diphtheria 10, in Milwaukee.

In 42 cities and towns of Massachusetts, with a population of 1,089,975 (population of the State 1,783,086), the total death-rate

for the week was 23.39, against 21.02 and 20.25 for the previous two weeks.

For the week ending January 15th, in 149 German cities and towns, with an estimated population of 7,706,995, the death-rate was 26.2. Deaths reported 3889; 1713 under five: pulmonary consumption 612, acute diseases of the respiratory organs 380, diphtheria and croup 190, scarlet fever 88, whooping-cough 64, typhoid fever 54, measles and röteln 44, puerperal fever 14, small-pox (Spandau, Königsberg, Munich, Nuremberg) 4, typhus fever (Berlin) two. The death-rates ranged from 17 in Darmstadt to 36.7 in Kiel; Königsberg 29.2; Breslau 28.7; Munich 33.6; Dresden 23.6; Berlin 24.8; Leipzig 23.4; Hamburg 26; Hanover 20.6; Bremen 25.3; Cologne 27.9; Frankfurt 22.8; Strasburg 24.7.

For the week ending January 22d, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 28.8. Deaths reported 4199: acute diseases of the respiratory organs 617, scarlet fever 103, whooping-cough 93, measles 72, small-pox (London) 22, diarrhoea 35, typhoid fever 32, diphtheria 13. The death-rates ranged from 19.5 in Portsmouth to 45.5 in Plymouth; Birmingham 23.6; Leeds and Bristol 24.3; Sheffield 24.8; London 28.4; Liverpool 35.6; Manchester 43.4. In Edinburgh 21.4; Glasgow 35.6; Dublin 45.7.

The meteorological record for the week in Boston was as follows:—

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 5, 1881, TO FEBRUARY 11, 1881.

GRAND, J. B., captain and assistant surgeon. In obedience to S. O. 14, C. S., A. G. O., relieved from duty in Department of Texas. S. O. 20, Department of Texas, January 29, 1881.

REED, W., captain and assistant surgeon. To accompany Battery 1, Second Artillery, from Fort Ontario — abandoned — to Fort McHenry, Md., and then report by letter to these headquarters for further orders. S. O. 25, Department of the East, February 9, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting will be held on Monday evening, February 21st, at eight o'clock, in the hall, 19 Boylston Place. Reader, Dr. Cutler. Subject, A Case of Fibrinous Bronchitis.

A. T. CAROL, Secretary.

THE censors of the Suffolk District Medical Society will meet for the examination of candidates at 19 Boylston Place, Thursday, February 24th, at three o'clock.

BOOKS AND PAMPHLETS RECEIVED. — Report of the Medical Director of the Department of Texas relative to the Soldier's Bation and its Increase under certain Circumstances.

Anæmia in Infancy and Early Childhood. By A. Jacobi, M. D. (Reprint.)

Coulson on the Diseases of the Bladder and Prostate Gland. Sixth Edition. Revised by Walter J. Coulson, F. R. C. S. London: J. & A. Churchill. 1881.

THE DIAGNOSIS OF LOCOMOTOR ATAXIA IN THE EARLY STAGES.¹

BY JAMES J. PUTNAM, M. D.

I AM well aware that in what I say to-night I shall bring forward nothing which is new to those members of the society who have had the time to follow, step by step, the recent developments in such special departments as these; and that, regarded as an exposition of the whole subject, the paper must necessarily leave unnoticed far more than it expresses, even of the discoveries which are of comparatively recent date. The practical importance of the subject must justify the attempt to present it in this imperfect form.

There is hardly a single organic disease of the central nervous system which has received the amount of study, within the past decade, that has been bestowed upon the affection which bears in England and America the name of its chief symptom, progressive locomotor ataxia, given to it by Duchenne in 1868, and in Germany the less compromising designation of wasting of the spinal cord, *tabes dorsalis*, an old and indefinite Hippocratic term, restricted by Romberg to this particular form of chronic spinal disease.

It is, perhaps, a little unfortunate that Duchenne, with his brilliant power of defining and formulating, thus riveted by a name the attention of the profession upon this symptom of motor incoördination; for the result has been that other symptoms, of no less real importance, have received a much less generous share of notice at the hands of the profession.

Among the rest, the *early signs* of the disease which is to occupy us to-night have not been adopted fully enough into the general conception of the affection, nor into the best books of general medicine.

It was formerly believed that there must be stamping with the heels and staggering with closed eyes, or no locomotor ataxia. Yet, as a fact, it may well be that ten or even twenty years before a sign or certainly anything more than an insignificant shadow, of this incoördination is to be made out, the disease, with its malevolent prognosis, is distinctly recognizable, and it is none too early to apply the appropriate treatment if it is to be of any avail.

The perfect insect and the larva are not, at once, nearer to and further from each other than the strutting, staggering ataxia, on whom every student makes a "snap diagnosis" in the street, and the man who comes to you for relief for a rheumatic trouble in his legs, which he has had for half a dozen years, and traces back to his grandfather's gout; or for incontinence of urine, which comes and goes; or for his failing eyesight, for which he accuses, perhaps, too much tobacco.

The difficulty of making a correct diagnosis is increased at this stage by two causes: first, because the symptoms bear a close resemblance, at times, to those of other diseases, — cerebral tumor, typical neuralgia, so-called idiopathic atrophy of the optic nerve, stone in the bladder, gastritis, organic disease of the rectum, rheumatism, even certain forms of mental insanity; and, secondly, because the patient, without intending it, does the best he can to throw the physician on to the wrong track. The theory which he has formed in

his own mind of the relationship between his various ailments is — though often positive enough, to be sure — quite different from that which the acute physicians of Europe learned to formulate only ten or a dozen years ago. So bent is his mind on the trouble which is at the moment uppermost that he may return an unhesitating negative to direct leading questions as to the existence of symptoms which a further cross-examination proves to have been harassing him off and on for five or six years back.

Especially true is this of the neuralgic pains, with which, in the vast majority of cases, the long and complicated drama opens. Unless these have been really severe, it will often be only after prolonged questioning that the patient admits a history of "rheumatism," as he always calls it, assuring you at the same time that it has been of no account; but ask him then to describe it, and, ten to one, he will do so in almost the identical, well-worn expressions of the classical treatises. The pains would come and go, he will say, with great rapidity, boring into the knee or the heel; or occupying a space on the fleshy parts of the thigh, in front, behind, at the sides, which could have been covered by the end of a finger; or grasping the leg as in a vice; then disappearing, to return again in a month or two, or before a storm, rarely, except in this latter respect alone, suggesting true rheumatism.

Before describing in greater detail the symptoms of the early stages of the disease, it may be well to sketch hastily the outlines of its pathology and clinical history.

The rule-of-thumb statement of the pathology of locomotor ataxia has long been that it consists in a sclerosis of the posterior white or fibrous columns of the spinal cord. This definition needs, however, circumscription. The morbid process is probably not, in the first place, a sclerosis, in the sense that the interstitial connective tissue is primarily or prominently affected, though it certainly is more or less involved, as are also the membranes over the posterior portion of the cord. Neither do the nerve fibres present to any great extent (Leyden) that histological appearance of increased density which has sometimes earned for them the name of being sclerosed. It is doubtful whether the term, atrophy (with Leyden), or inflammation (with Charcot), is the best to designate the change which the tissues undergo, but the important point, and one on which most observers are now agreed, is that the process is, at any rate, a primary affection of the nerve fibres themselves.

With regard to its distribution, although in later stages of the disease the whole area of the posterior columns is usually involved, this is true in the beginning only of restricted portions, which I have drawn upon the blackboard; those, namely, which are known as the internal radicular fasciculi, or, following the French terminology, the zones of the posterior nerve radicles, or the *bandelettes externes*. Disturbances of the other parts of the posterior columns may occur without causing either the ataxia of movement or the sensitive disturbances which are characteristic of locomotor ataxia.

It is to Charcot and his pupil Pierret that this discovery is due, and its importance will at once be seen when it is remembered that disease is thus performing a physiological experiment of the greatest nicety. We have three cardinal symptoms to explain, — pain, alterations of sensibility, and incoördination of movements; and all are due, if this observation is correct, to disease

¹ Read before the Boston Society for Medical Improvement, February 14, 1881.

in these little bandelettes of fibres. The two former are readily referable to irritation or destruction of fibres coming directly from the posterior nerve roots, which are known to enter largely into the composition of these fasciculi (whence, indeed, their name). When absolute loss of sensibility occurs it is usually inferred that the posterior cornua are involved likewise. The explanation of the ataxia is less easy, and need not be discussed here, but it is clear that accurate anatomical investigations such as these are likely to help largely towards its discovery.

Besides these portions of the posterior columns, it commonly, if not always, happens, as stated, that the posterior nerves themselves are affected; often the neighboring meninges; eventually, the entire area of the posterior columns; and occasionally the posterior gray cornua, the neighboring portion of the lateral white columns, and even localized spots in the anterior cornua, though very exceptionally. In this manner not only the spinal cord in its whole length is attacked, but parts placed still higher in the cerebro-spinal axis.

Temporary paralyses of almost all of the other cerebral nerves are common, deafness and loss of smell occasionally occur, but I am not aware that an anatomical explanation for these symptoms has actually been demonstrated, except in the case of the first, third, and fifth nerves.

The lesion of locomotor ataxia seems to stand, moreover, in a close relationship to that of the progressive paralysis of the insane, a disease which has an organic lesion of the brain as its basis, and this undoubtedly accounts for certain of the motor disturbances met with in that extraordinary disease.

It is less common for mental symptoms to appear as forerunners of a typical locomotor ataxia; the latter finally becoming the principal affection, but this too is met with, as I shall be able to illustrate.

Clinically, the history of a typical case of locomotor ataxia is usually regarded as divisible into three stages, which shade into one another by imperceptible gradations.

The first stage is that of the neuralgic pains, the optic atrophy, and the rest of the symptoms which interest us to-night.

The second stage is that of the ataxia, or rather of the fully developed affection, since the neuralgia continues into this stage also.

The third stage is that of prostration, amounting sometimes to utter helplessness, and, it may be, muscular paralysis and atrophy, and is marked by the occurrence of such signs as cystitis and bed-sores, under the influence of which the patient gradually succumbs.

The frequency with which this disease is met with is considerable. Thus, in the past five years we have had twenty-six well-marked cases in the out-patient department for diseases of the nervous system, out of a whole number of 2650, forming about one per cent. of all who applied for treatment.

The early symptoms which are especially deserving of notice are the following:—

- (1.) Neuralgia in the extremities and trunk.
- (2.) Visceral paroxysms, characterized by pain and the attendant symptoms of functional disturbance.
- (3.) Symptoms relating to the eye and other organs of special sense.
- (4.) Absence of the tendon reflexes.
- (5.) Mental disturbances.
- (6.) Alterations of sensibility of the skin.

(7.) Alterations of nutrition in the bones.

(8.) Cardiac disturbances.

Of all these early symptoms the neuralgic pains are the most common, and are likewise among those that appear the first. Out of one hundred cases observed by Erb and Buzzard they were absent but seven times. I have characterized them briefly already, and shall say but a few words more about them. They are distinguished both by the presence of their own features and by the absence of those which belong to pains of other origins, with certain well-recognized exceptions. As for the former mark, Charcot divides them into boring, lancinating, and constricting pains, and it is only the latter that are at all persistent, the former coming and going, either like a flash, or with a gradual rise and fall from zero to maximum and back. Their severity is at times such—especially when they are deeply seated, about the joints or in the heel—that I think they must equal the pain of the thumb-screw and the rack. Such similes as the “gnawing of rats,” “boring with a red-hot corkscrew,” which I quote from Dr. Buzzard, are very common. I remember well a private patient suffering for years from these pains, of such intensity that at every recurrence, though a man of great fortitude, the leg would be thrown convulsively in the air and the face contracted into grimaces of acute distress, the whole subsiding in a few seconds, and leaving no trace, except a worn expression of suffering. Their severity is by no means, however, their most characteristic feature. They may be present from the crown of the head to the sole of the foot, and each locality has its favorite modes of suffering.

Still it is in the legs that they are the most common, and if I were asked what, in the statements of my own patients, had most struck me with reference to them, I should say that it was the fact that they come and go, now here, now there, and are often felt in limited spots in the fleshy parts of the thighs, removed from any sizable nerve, which is so unusual in other forms of neuralgia. It is no doubt true that similar pains may occur in other spinal affections, especially Pott's disease and disseminated sclerosis. Still, if they only help to make us look for further differential signs, they will have served a good and usually a sufficient turn.

It is a common occurrence to hear patients speak of having had these pains for five or six years before any change of gait was observed, and this interval may even be extended to ten, fifteen, or twenty years; otherwise the disease may even be arrested at this stage, forming one of the so-called abortive forms, and yet at the autopsy the characteristic lesion be discovered.¹ One or two other points, less often insisted on, are worthy of consideration here.

It is very true, as Buzzard has pointed out, that, in face of the richness in symptoms which many of these patients are found to present, the moment the attempt is made to go into them in detail the more striking ones draw off the attention from others which, when they occur by themselves, may be of equal diagnostic value. This is true, for example, of the alterations in sensibility, which an accurate observer has discovered to be regularly present not only in the extremities, where they are usually sought for, but all over the trunk, front and back, as well.

In like manner, Buzzard finds neuralgia in the distribution of the fifth and the trigeminal nerve and the great occipital nerve to be commoner than one would

¹ Charcot, *Maladies du Système nerveux*, ii. 13. Pierret, Debove.

gather from the usual descriptions, and anæsthesia of the face is occasionally met with.

The occipital nerve is given off by the second cervical, and comes, therefore, within the limits of the spinal cord. The fifth nerve likewise, though its main origin is much higher, is known to send a root down as far as the junction of the spinal cord and the medulla, a patch of disease has actually been found in this very neighborhood.

How shall these neuralgias, which suggest so gloomy a prognosis, be distinguished from the benigner sorts, which are so very common in the regions referred to?

Buzzard lays down the following proposition, which it will be both convenient and important to remember: "Flying, so-called neuralgic pains in the head, then, when they attack both sides, and do not map out the district of one or other division of the fifth nerve, should lead to attentive examination for symptoms of tabes."

Another matter, of almost equal interest, is the differential diagnosis of locomotor ataxia and tumor of the brain. Both affections may cause intense pain in the head; and both are very apt to cause blindness, due to atrophy of the optic nerve.

Furthermore, Charcot points out that cerebral tumors are not unapt to cause flying pains in the extremities and all over the body, which might easily be mistaken for the lancinating pains of tabes. An important differential diagnostic mark — and it might happen to be the only one — is this: that, whereas the optic atrophy of tabes is, as we shall presently see, a simple atrophy, the atrophy from tumor is the result of neuritis, and usually bears the stamp of its origin in obscure disk outlines, tortuous veins, and increased connective tissue about the arteries. Charcot reports a case where, but for this, the diagnosis would have been well-nigh impossible, and Buzzard another illustration of the same point.

I say that these signs are usually sufficient to distinguish between these different varieties of atrophy. Often enough, however, as Buzzard admits, and oftener than Charcot's brilliant, but somewhat over-colored, description would suggest, the signs of neuritis clear entirely away after a time, so that the origin of the atrophy is no longer to be made out.

Equally characteristic are the visceral attacks or paroxysms, or *crises viscérales* of the French, the termination *algia* not sufficiently indicating the true nature of the seizure. When it is the stomach that is thus attacked there is atrocious abdominal pain, nausea, vomiting and retching, or sometimes vomiting without the pain, lasting for hours at a time, and off and on for days; yet, in spite of it all, the moment the attack is over the functions of the stomach are usually performed as well and regularly as if nothing had happened. One case of this kind has been in the outpatient department, one very well marked one in the wards, of the Massachusetts General Hospital, within the past year or two.

If it is the rectum about which the symptoms centre, there is usually intense tenesmus, with occasionally an involuntary discharge of feces, and the severe and sickening pain takes on a character which suggests the introduction of some huge, blunt instrument into the cavity of the organ.

If the vesical plexus of nerves is involved there is frequent and painful desire to pass water, and pain also during the act; and there is apt to be slow and imperfect

evacuation of urine, and also a sort of incontinence, which causes frequent dribbling, or probably, in reality, frequent sudden passages of small quantities of water rather than true dribbling. There is perhaps not a single one of the different species of bladder symptoms that may not occur in this connection. The pain may be referred in part to the end of the penis, and many of the symptoms may simulate strongly vesical calculus.

I recall one case that had been examined carefully, with this diagnosis in view; and another, in a woman, who had been treated — justly enough, for all I know — for uterine disease. In both, when I saw them, the signs of locomotor ataxia were unequivocal, though in the man, confined, if I remember rightly, to the presence of the typical eccentric pain in the legs and loss of the patella reflex. Hutchinson reports a case where the bladder symptoms on account of which the patient applied simulated exactly those of hypertrophy of the prostate. Or it may be the passage of a renal calculus which is thus mimicked, with all its attendant features, such as vomiting and elevation of the cremaster. (Raynaud, Dieulafoy, Lereboullet.)

This subject is justly reviewed by Dr. T. B. Curtis, in the Report on Urinary Surgery, published in the Boston Medical and Surgical Journal, for 1879 (vol. ii. p. 479), and its practical surgical importance pointed out.

The difficulties of this differential diagnosis are made no easier by the fact that not only toward the end of the disease, when purulent cystitis and sometimes pyelonephritis is said to be present, but also in the earlier stages, there is at times a vesical catarrh, due perhaps to the partial retention of the urine.

It is rarely, if ever, true, however, of the other viscera that they are the seat, under these circumstances, of organic disease, and this fact alone is usually enough to suggest the diagnosis. We have in both cases to deal with a renal or gastric colic, etc., but in locomotor ataxia the pain and functional symptoms are of central origin; in case of renal calculus or gastritis, they are of peripheral, that is, of reflex, origin.

Years may elapse, during which these symptoms, usually with others, such as the pains in the extremities, exist without any sign of motor disturbance. There are other symptoms associated with these which I have mentioned, many of which are given in the brilliant and classical descriptions of Charcot, in his *Maladies du système nerveux*. Among them is a quickening of the pulse, without fever, which throughout is apt to characterize locomotor ataxia, and counts as one of the signs of affection of the sympathetic system, to which the changes in the size of the pupil, to be referred to later, are in part due, and other symptoms as well.

Not only the abdominal, but the thoracic, viscera are liable to be similarly involved, the symptoms being those of asthma-like seizures, palpitation of the heart (certainly in connection with gastric attacks), or spasm of the larynx. (Krishaber.)

(To be continued.)

— Old gentleman (military man, guest of the squire's, conversing with smart-looking rustic): Wounded in the Crimea, were you? Badly? Rustic: The bullet hit me in the chest, here, surr, an' came out at me back! Old gentleman: The deuce! Come, come, Pat, that won't do! Why, it would have gone right through your heart, man! Rustic: Och, faix me heart was in me mouth at the thoine, surr!

THE CARE OF INSANE CRIMINALS.

BY WALTER CHANNING, M. D.¹

THE study of criminal insanity has been but little pursued in this country, and this fact accounts, in part, for the large number of insane persons who find their way to prisons and jails. It is far from being a recognized truth that crime is often a mere development of mental weakness, and hence we find judges very seldom considering the possibility of insanity in petty cases, and, as a consequence, unwittingly sentencing insane persons to prison. I doubt if we shall ever investigate the psychology of crime thoroughly until we have well-managed asylums for insane criminals; for it must still be many years before we can expect these physicians, who have the most to do with criminals, educated to the point where they will appreciate the intimate connection of crime with insanity. These words apply especially to prison-physicians, "whose chief study should be psychology," as was said by a distinguished Scotch prison-physician.

In a paper written for the conference of charities in 1879, I endeavored to show how the general class of insane criminals (which term I use both for those who committed crimes when sane and became insane after conviction, and those who were insane when the crime was committed) formed, in most ways, a distinct class of the insane by themselves. Every one will acknowledge that there is a criminal class, whose members are unfitted to associate with other members of the community, and if such persons are convicted of crime, sent to prison, and become insane, as a matter of principle no one would admit that they were any more fitted to be introduced into ordinary society. In practice, however, we do ignore this simple fitness of things, and are willing so have them sent into the same hospitals with the most pure and refined persons. As Dr. Bourdin recently said at a meeting of the British Medico-Psychological Society, "mental alienation does not suppress man as a moral and intellectual being. It disturbs and modifies him in various ways, without annihilating in him the fundamental faculties of his essentially human being. Under the cloak of insanity, one finds man with his own qualities, with his faults, his vices, and his virtues." Dr. Tuke, in commenting on these words, says, "that these observations find their best application in prisoners who have become insane, lunatic prisoners."

About the disposal of the second class of *innocent* insane criminals — if such a contradiction of terms will be excused — there must still be considerable doubt. Objection is often made to calling such persons insane criminals; but they have inflicted an injury to society which amounts to a crime, and though morally innocent, the term still applies to them. This class is largely composed of true criminals, the insanity seeming to break down the little self-control which had previously kept them from openly violating the law. Often their bad course of life led to the attack of insanity, — an assertion verified by experience. Belonging to this class there are also many weak minded persons, imbeciles, and epileptics. Mental defect comes to them as a bad heredity from dissolute or diseased parents, and generally belonging to the lower orders, they are still further unfitted to associate with

the ordinary insane. Throwing out these various subdivisions of the class under consideration, we have left a small residue of persons of upright and respectable character, who may be truly called victims to their disease. These persons are the ones to be really pitied, and their individual cases require prolonged consideration. In sending them to hospitals, reference should be made to their mental state alone. If harmless, and likely to continue so, there can be no reason for not sending them to an ordinary institution, the decision being left to the court, on proper expert testimony. Should the slightest doubt, however, still exist, these persons, in justice to the great body of the ordinary insane, should go to the criminal asylum.

In the Boston Medical and Surgical Journal of November 11th, there was an editorial referring to the defective arrangements at present existing for the care of insane criminals, more especially in Massachusetts and Vermont, and mention was made of a late message of the Governor of Vermont, in which the present method of treating this class at an ordinary institution was spoken of as a matter needing reformation. It might have been added that the same bad system prevailed throughout the whole United States, with the exception of New York. This bad system has been a theme of discussion on the part of asylum authorities for the past thirty years. For many years asylum superintendents, in their annual reports and at their annual meetings, have constantly written and spoken on the difficulties and dangers arising from treating the ordinary with the criminally insane. As long ago as 1873 the following resolution in reference to the Care of Insane Criminals was passed by the Association of Asylum Superintendents: "*Resolved*, That neither the cells of penitentiaries, nor the wards of ordinary hospitals for the insane, are proper places for the custody and treatment of this class of the insane." At the annual meeting of the British Medico-Psychological Society held in the same year, it was moved "that this association take steps to prevent criminal lunatics being sent to county asylums."

This resolution referred particularly to the convicted insane, for the reason that the unconvicted, or "lunatics detained at her majesty's pleasure," were already provided for at the Broadmoor Criminal Asylum, leaving, therefore, the mass of the convicted to be cared for at the county asylums. Matters have gone from bad to worse in England until, in 1879, there were over twelve hundred criminal lunatics in the county asylums.

To more fully demonstrate the evils of the treatment of insane criminals at ordinary hospitals for the insane, I desire to give extracts from an excellent letter of Dr. John W. Ward, superintendent of the New Jersey State Lunatic Asylum at Trenton, N. J., who for some time has had a large number of insane convicts under his charge, and hence is in an admirable position to pass judgment on their treatment. Dr. Ward thinks that the unconvicted can be treated with the ordinary insane; but from what I have already said it will be seen that my experience has been different. Dr. Ward's statements, in my opinion, apply very generally to the whole class of the criminal insane.

Dr. Ward writes as follows: "We at present (April 3, 1879) have thirty-four of this class (of the convicted insane) under care in this institution; and from actual experience, and not theory, I think I am justified in saying that the present system in vogue, of treating the convict class in an ordinary hospital for the insane,

¹ Read December 1, 1880, before the Boston Medico-Psychological Society.

² Vide an article by Dr. Hark Tuke in the Journal of Mental Science for July, 1879.

is most unjust and undesirable. Your first question, Are they (the convicted insane) more care than the ordinary insane? Decidedly, if treated in an ordinary hospital for the insane. The custodial care of this class, as you readily see, is a matter of much greater importance than the care of the ordinary insane. Many of these people are professional house-breakers and thieves, many of them murderers, persons most undesirable to have turned loose on society; and hence the necessity of making special provision for their detention. To do this, and introduce the fewest possible features of a state prison, we have the corridor set apart for this class double-locked, and with a double force of attendants. We have here three or four attendants, as the case may be, to two attendants on a corridor where there are no convicts. The superintendent of a hospital in this State is made amenable, should an escape occur of one of this class, to the same laws, and subject to the same penalties, as the keeper of the state prison. . . . Our hospitals are not constructed for their custody, and it is not desirable to introduce the ordinary features, even, of a prison into a hospital for the sick. They are more care, also, in their treatment apart from the mere custodial care. They are, as a rule, bad people prior to their insanity: the exceptions to this are very few. They are, according to our experience, greatly more quarrelsome, more filthy, and in every way more ungovernable, than the ordinary insane. The proportion of troublesome patients is infinitely greater among the convict class. This is not surprising. Insanity does not usually make saints of those who have led lives of vice."

It is needless to produce further testimony from hospital superintendents, as it would be of a similar tenor, and perhaps less clearly expressed. It is safe to say that the universal opinion is in favor of separate institutions for all of the *convicted*, and for a very large majority of the *unconvicted*, insane, and it is equally certain that such institutions cannot be carried on properly either in connection with asylums or prisons. If treated in a building connected with an ordinary hospital, the insane criminal may still exert a prejudicial influence on the inmates of the institution, and cannot receive the care and attention, and be given the liberty and freedom of action, that he is entitled to. He still belongs to an exceptional class, and will be treated in an exceptional manner. If treated in a special department of a prison he is even more unfortunate. He becomes doubly a prisoner, for he is watched, suspected of feigning, feared, and often maltreated. He will be kept locked in his cell, receive poor food, and may possibly be beyond recovery before his disease is recognized, and he is regarded as a sick man. Prison physicians being generally, as I have already said, men of limited education, they take a narrow, ignorant view of insanity, and leave its diagnosis to the prison-keeper, who is apt to regard every convict as a cunning sort of devil, who committed a crime largely for the purpose of getting into prison to impose on his credulity. Woe to the convict who is mildly insane! Then at the best he is only "playing it," and is subjected to just the harsh treatment that fans the flame of his disease. It has usually been my experience that convicts are not regarded as actually insane until they perform acts of violence which make them feared. The keeper, then, becoming suspicious, consults with the doctor, who agrees with the keeper that the man is dangerous, and he is shut in his cell, possibly hand-

cuffed in addition, and occasionally visited and watched through the grating of his door, like a dangerous animal. In New York the Asylum for Insane Criminals at Auburn is a *dernier resort*, and the convict, if sufficiently violent, may hope for transferral while his symptoms are acute and there is a chance for recovery. If, however, they take the form of depression, with delusions that are with difficulty drawn out, the chances are that his transferral will take place too late. It is not much to be wondered at that the convict can hope to receive so little individual attention, for in our prisons we usually find one physician to from five to fifteen hundred convicts, and then he gives only a part of his time to them. When we properly reform our prison systems of management, as a glance at some of them will show we are yet far from doing, we shall first appoint efficient medical men as prison physicians, then pay them well, and make them residents.¹ We shall then know just how many insane persons there are in our prisons, and obtain a scientific knowledge of prison diseases and criminal psychology. In all States but New York the insane convict has a gloomy and hopeless future, for if violently and dangerously insane he will be considered such a *mauvaise sujet* that he will be doubly locked in his cell and chained, and have no chance of transferral to an ordinary hospital on the score of *too dangerous*. If mildly insane the case will be nearly as bad, for he will then suffer from neglect, and, being harmless, the prison officials will say "We can keep him; he won't hurt any one."

For these reasons, then, it is obvious that we need hospitals separate from all other institutions for the exclusive use of criminals. Some persons, on superficial investigation, suppose that there are not enough insane criminals to warrant the erection of hospitals, but in 1879 I found eighty-four persons belonging to the criminal class in Massachusetts hospitals. This number could be largely added to if all the penal institutions in the State were carefully examined, and all persons whose mental condition could be improved by residence in a criminal hospital were removed to it. Different authorities would of course entertain different views on this subject, but, speaking from experience, there are many imbecile, weak-minded, or epileptic criminals, now harmless inmates of our penal institutions who would be benefited, and, in time, even made fairly useful members of society, if treated in such an institution as that at Auburn was two years ago. If our judges could send weak-minded or partially insane criminals to a criminal hospital the number of inmates would be increased, and our courts relieved of one source of anxiety. There would be a further class of dipsomaniacs who could also be advantageously placed together in one ward in such an institution. Not all dipsomaniacs, but a certain incorrigible set, who cannot be managed in an ordinary hospital for the insane, and are even more difficult to control when at large. A special law adapted to this class might then be necessary.

For large States, like Pennsylvania and Illinois, there should be hospitals large enough to accommodate two hundred patients, but in our smaller New England States so large a number could not be found in one State, and two or more States could therefore combine together and use one institution in common. Massachusetts, for instance, could provide a suitable

¹ I do not mean to say that there are no well-educated physicians connected with prisons; to this rule, as to others, there are of course exceptions.

building, of a capacity of from one hundred and fifty to two hundred patients, and receive boarders until the State required all the room. The New York institution formerly received United States insane convicts as boarders, but I think has now a sufficient number from her own State. Should a new institution be erected in Massachusetts, one wing could be at first finished and occupied, and then the remainder of the work done from year to year, chiefly by the patients, as occasion demanded.

As a site for a building, a good-sized farm, in rather an isolated part of the country, should be selected. The building should be absolutely fire-proof, and built generally in a more substantial manner than the ordinary hospital for the insane. There should be separate buildings for the sexes, and perhaps an isolated building for the working patients, and either a ward, as I have already said, or, perhaps, what would be better, a separate building, for the dipsomaniacs or insane drunkards. The building should be cut up into numerous small wards for not more than ten patients, and there should be no dormitories, as criminals abound in bad practices, which they can indulge freely in if placed together. One ward should be isolated from the rest, with rooms on one side only. These rooms should have every possible arrangement for preventing escapes, and "observation holes," through which patients could be watched. It happened with us at Auburn that there were, at various times, several feigners, and these "observation holes" were of great service in enabling us to detect imposture.

Into fuller details of construction it is at present unnecessary to go, especially as in this State the expediency of using some old building, which has outlived its usefulness, has been suggested.¹ The county receptacle at Ipswich, among others, has been mentioned as a fitting place. Combining, as it does, the jail and the insane receptacle, it might possibly be remodeled at a small expense. To start at the outset with the best plan of arrangement, it would be necessary to do away with everything suggestive of the prison; if this can be done at Ipswich, and the amount of land is sufficient, and a fair amount of seclusion attainable, it will undoubtedly be better to begin there than to wait indefinitely for a new building.

In a criminal asylum the discipline and general treatment of patients are of the first importance, — of even greater importance, I might say, than at an ordinary insane hospital. Coming, as most of the patients do, from some place of imprisonment, they are physically much reduced, and either timid and frightened, or rebellious, threatening, and suspicious of all officials. The main points of treatment will be, first, to make the patients bodily comfortable, and then to instill a spirit of confidence into them. To carry out the first point of treatment is not difficult, and the good results of thorough bathing, good food, and a soft, clean bed are really marvelous. At Auburn our patients could bathe as comfortably as in a private house, and having come from prisons, where, they said, they had never bathed, it was a revelation to them. One of our chief pleasures was to go into the wards, and visit new patients the morning after their arrival at the asylum. Instead of the gloomy, scowling, dirty convict of the previous night, we would often find a cheerful and hopeful, and always a clean patient.

The moral treatment of the insane criminal is far

more difficult than that of the ordinary insane, for in addition to the perversion of disease we have to fight against inherited depravity and acquired vice in every conceivable form. These bad traits crop out in the most unexpected places, and lead to complications unknown in the ordinary asylum. Consequently the criminal character requires extended study in order to discover the key which will enable us to make the best of what there is in it. Once having found the key and we shall find the criminal asylum almost as easy to manage as the ordinary insane hospital. Kindness, which is generally quite unknown to the ordinary convict, is highly appreciated, and will be one of the chief means used in dealing with his disease; but with this kindness there must be a discipline which, without being rigid, will be more firm than that which is necessary in the management of the ordinary hospital for the insane. To illustrate what I mean, I will briefly describe the management of the patients at the criminal asylum at Auburn. In the first place a uniform dress was worn, but of such an unobtrusive character as to be hardly noticeable. It consisted of a soldier's blue blouse, gray pantaloons, and vest, which made a very neat costume, cheaply and easily provided, and in case of an escape (a common occurrence at a criminal asylum) it served as a valuable means of identification. The convicted patients wore no beards, for being still convicts in the law, and on recovery before the end of sentence returnable to prison, it was best to make no change. No knives were used at table, as they would be used as weapons, made into saws for cutting bars, or stolen from the force of habit. With the rarest exceptions no patients went outside of the grounds, and with the exception of those who worked on the grounds none were allowed outside of the airing courts. On coming in from work patients were carefully searched, as they had a habit of smuggling in a great variety of articles. The rooms were devoid of all furniture with the exception of a bed, in the majority of cases, though from this rule we made numerous deviations. Patients rarely saw their friends alone, but usually in the presence of an attendant, or the supervisor. It should be said that we invariably deviated from these rules when the circumstances of the case allowed. We were anxious to give the patients every possible liberty, but felt our great responsibility to society in holding the worst and most dangerous classes of criminals.

The above rules applied especially to men, as out of the one hundred and twenty patients not more than twelve to fifteen were women. For these even more stringent rules were necessary, as they all belonged to the lowest of social orders, had usually led lives of immorality, and were subject to frequent outbreaks of violence.

The use of restraint under Dr. C. F. MacDonald, at Auburn, was gradually abolished, and in the year 1878 almost none was used.² Though Dr. Orange uses no restraint at Broadmoor in England, he has a less violent class to deal with than that found at Auburn; and Dr. MacDonald should certainly be congratulated on reducing restraint from about ten per cent. in 1876 to so little in 1878. He states that this arose partly from an accidental state of affairs, and though he prefers to use no restraint, yet another year he might have found it necessary. This favorable showing might have been partly accidental, but the true cause of such tranquillity among the patients arose from the conversion of the

¹ January 8th. See the governor's message of the 6th inst.

² One per cent.

asylum from a branch prison into a hospital, with its excellent moral and hygienic surroundings. Success like this should certainly encourage us to hope for the speedy establishment of a criminal insane hospital in our own State.

The Auburn asylum was built in 1859, and was placed under the charge of the New York State Prison Inspectors. This form of organization was most unfortunate, as it subjected the asylum to the baneful influence of politics. Furthermore, the inspectors were chiefly occupied with prison affairs and gave but little attention to the asylum, which they regarded as only a small branch of the neighboring immense prison. In 1876 the Board of Inspectors was abolished by constitutional amendment, and a superintendent of state prisons, supposed to be a non-partisan officer, was appointed by the governor. This officer has the same power as the old board of inspectors, but I should suppose had very little time to give to matters appertaining to the asylum. Such an institution should have an organization entirely independent of the state prison, and should be managed by a board of trustees, as is common in our ordinary insane hospitals. A board of five would be sufficiently large. Of these it would be well to have one or two appointed from the board of commissioners of prisons, and the rest should be men who had had experience in hospital supervision. With a mixed board of this kind an active interest and inquiry into prison affairs would be engendered, and at the same time there would be no danger of making the hospital into anything but an institution for the treatment of disease.

I give below several extracts from the laws of New York bearing on the subject of insane criminals, as being of interest and importance in the discussion of the question of suitable provision for this class.

First, the Commitment of the Insane by Criminal Process, article second, title first, chapter 446. Laws of 1874:—

"Section 22. If any person in confinement under indictment for the crime of arson or murder, or attempt at murder, shall appear to be insane, the county judge of the county where he is confined shall institute a careful investigation, call two or more respectable physicians and other credible witnesses, invite the district attorney to aid in the examination, and, if it be deemed necessary, call a jury, and for that purpose is fully empowered to compel the attendance of witnesses and jurors; and if it is satisfactorily proved that such person is insane, said judge may discharge such person from imprisonment, and order his safe custody and removal to one of the state lunatic asylums, or to the State Lunatic Asylum for Insane Criminals, at the discretion of such judge, where such person shall remain until restored to his right mind, and then if the said judge shall have so directed, the superintendent of said asylum shall inform the said judge and the district attorney of the county thereof, so that the person so confined may, within sixty days thereafter, be remanded to prison, and criminal proceedings be resumed, or otherwise discharged.

"Section 24. Any person who is now, or shall be hereafter, confined in any penitentiary, and who shall appear to be insane, may, on application of the superintendent thereof, be transferred to the State Lunatic Asylum for Insane Criminals at Auburn, under an order of any justice of the supreme court, or the county judge of the county in which such penitentiary is located, upon satisfactory evidence that such person is insane; and the judge shall thereupon order his removal forthwith to said asylum, where he shall remain until recovered, or otherwise discharged according to law.

"Section 25. The penitentiary from which such convict shall have been transferred shall be liable for the expenses of his care and maintenance during the time he shall remain in said asylum, provided that he is removed therefrom before the expiration of his sentence. If he shall continue insane after the expiration of the time for which he was sentenced, then the county from which he was sent to said penitentiary shall pay his expenses, as is hereinbefore provided in section twenty-two."

The following are extracts from the laws concerning admission and discharge of convict patients from the state prisons. Section 6 *et seq.*, title viii., chapter 594. Laws 1875:—

"Section 10.¹ Whenever the physicians of either of the state prisons of this State shall certify to the board of inspectors, or to the inspector in charge, that any convict therein is insane, it shall be the duty of such board or of such inspector in charge to make immediately a full examination into the condition of such convict, and if satisfied that he is insane the said board of inspectors, or the inspector in charge, shall order the agent or warden of the prison where such convict is confined forthwith to convey said convict to the State Asylum for Insane Criminals, and to deliver him to the superintendent thereof, who is hereby required to receive him into the said asylum, and retain him there until legally discharged.

"Section 12. In case the insanity of any convict shall continue after the expiration of his sentence, he shall be retained in said asylum until adjudged a fit subject to be discharged by the state commissioner in lunacy.

"Section 13. Whenever any convict, who shall have been confined in the said asylum as a lunatic, shall have become restored to reason, and the medical superintendent of said asylum shall so certify in writing, he shall be forthwith transferred to the Auburn State Prison, and the agent and warden of said prison shall receive said convict into the said prison, and shall in all respects treat such convict as if he had been originally sentenced to imprisonment in said prison, though said convict may have been conveyed to the said asylum from either of the other prisons of the State, but any convict received from a penitentiary shall be returned to the same."

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. LYMAN.

REPORTED BY DR. JOHNSON, HOUSE OFFICER.

CASE IV. VESICO-VAGINAL FISTULA.

MARY R., thirty-three years of age, entered hospital December 14, 1880, with following history: Was married in Scotland seventeen years ago, and in nine months had her first child, after a labor of three days terminated by the forceps. At the end of three weeks the urine began to dribble away involuntarily. She then entered the hospital at Greenock and remained eighteen months, during which time the fistula was twice operated upon without success, and she was discharged, as she says, incurable. Since that time she has been delivered at full term six times, and once, the last time, of a six months' fetus, making altogether eight pregnancies. During this long period she has suffered the usual distress and inconvenience incident to the constant dribbling of urine. In June last she was in the City Hospital for a short time with a pelvic effusion, originating in a fall, from which she soon recovered after removal by aspiration of sixteen ounces of fluid by Dr. Blake. Since that time she has undergone another operation in this city for the fistula, which also proved unsuccessful, and for some reason, which she does not explain, probably her own fault, the sutures were never removed. She now enters on account of headache, backache, and slight febrile symptoms, and desiring to have the sutures removed, as they naturally are not agreeable to her husband. Quite recently, two months after the last operation, she miscarried at six months. She declines any further inter-

¹ Section 10 is simplified at the present time. Under the inspection it was sometimes necessary to wait weeks for the signature of one of the board. Now the power of transfer is practically in the hands of the physician and warden.

ference, as the leakage "never ceased for a single day" after the previous operations.

December 16th. Upon examination, four deep wire sutures placed transversely near the cervix, presenting a *chevaux de frise* were found and removed. The fistula high up on the right anterior vaginal reflection from the cervix allowed a free flow of urine.

December 22d. Having finally determined to submit to one more attempt she was etherized and the edges freely denuded longitudinally. Resting upon the mucous membrane of the bladder, crossing the fistulous track, was a piece of wire suture five eighths of an inch in length, which had been left from the previous operation. Four sutures were now carefully introduced, lengthwise of the cervix, effectually closing the orifice.

December 29th. The sutures removed and catheter discontinued. She was directed to evacuate the bladder every four hours.

January 7th. Discharged well.

The case is interesting only from the fact that she had seven successive pregnancies, notwithstanding the foul secretions from the constant presence of urine in the vagina; from an operation at the fourth month without miscarriage; from the accidental presence of a foreign body preventing union, and from the birth of a six months' child without any disturbance of the unremoved sutures close to the cervix.

CASE V. EPITHELIOMA OF CERVIX UTERI.

M. B., aged twenty-five, entered hospital September 28, 1880, married,—one child two and a half years ago,—gives a history of pain, and irregular menstruation for past two years, and more or less metrorrhagia. Has had steady "heavy" pain for past three months. For a year has had a watery discharge from the vagina, and for past four months this has been offensive. Now suffers from dysuria and diarrhoea. Examination revealed a large mass of cauliflower excrescence attached to cervix, the greater portion of which was easily removed with the finger. This was followed by hamorrhage, and so much exhaustion as to require the application of solution of subsulphate of iron, and the removal of the rest was not attempted.

October 2d. Greatly relieved by the operation, the pain and discharge being much diminished.

October 5th. The operation was repeated and the surfaces were scraped with the curette.

October 6th. Expresses herself as feeling all well. Was ordered generous diet, hot carbolized douches, and morphia, with injections of chloral at night.

October 19th. Has offensive discharges, and has suffered a good deal from pain.

October 24th. Has less pain, though she suffers from dysuria, and on the 27th was discharged at her own request.

CASE VI. EPITHELIOMA OF CERVIX UTERI.

L. I. E., a stout, healthy looking woman, aged fifty-one and married, entered hospital as private patient November 13, 1880. Has had two children. A year ago she had a slight attack of flowing which lasted three days, in January had a second hamorrhage, flowing profusely for three days. Since that time has had but little pain, but a thin watery discharge has continued from the vagina. In May the discharge became offensive for a time, but has now been free from it for four months. The bowels are constipated

and defecation difficult. Is troubled most by pressure upon the bladder and difficult micturition. Examination revealed a mass of epithelioma, as large as a hen's egg, attached to anterior lip of cervix and pressing hard upon the bladder. This was removed with the *écraseur*, when it was found that the disease extended well up to the uterine cavity. The whole was carefully enucleated away with Simon's spoon, and the surfaces packed with pledgets of cotton soaked in solution of subsulphate of iron. The following day the temperature rose to 103.5° F. Quinine in five grain doses was given and the tampons removed.

Nov. 15th. Much relieved; no dysuria; to have hot carbolized douches.

Nov. 19th. Discharged at her own request entirely relieved of pain and dysuria, with directions as to frequent examinations for removal of new growths.

CASE VII. LACERATION OF CERVIX UTERI AND PERINEUM.

J. W., thirty-eight, married, entered hospital October 21, 1880. Had a miscarriage five months after marriage, and five living children since, the last, four years old, after an easy labor of six hours. Catamenia always irregular. Has lost much flesh and strength, has a cough, night-sweats, headache, and much leucorrhoea, with pain in back and bearing down. Nothing positive discovered in lungs on auscultation. Has been confined to bed for past month from debility. Upon examination the cervix was found to be lacerated bilaterally, with the mucous membrane swollen and everted, and the perineum torn down to the sphincter. Uncertain as to which labor caused these injuries. She was ordered tonics, generous diet, rest in bed, carbolized douches, and laxatives as required. A month of this treatment relieved the cough and debility, and December 10th the lacerated cervix was denuded and drawn together with six wire sutures. On the 17th four sutures were removed, and the next day the remaining two.

October 28th. Cervix found to be perfectly united. Patient much improved in every respect, and advised to delay interference with the perineum until after a period of recuperation outside the hospital.

CASE VIII. LACERATED CERVIX UTERI AND PERINEUM.

H. B., thirty-six years of age and married twelve years, entered hospital November 6, 1880, for the third time. She has suffered from retroversion, dysmenorrhoea, dysuria, and the usual symptoms of pelvic congestion for some years, from which she gets no relief by general measures, and desires a more radical treatment. She has had three miscarriages and six living children, the last now four years of age. Dates her troubles from this last labor, though it was not a severe one. Was last unwell three weeks ago.

November 8th. Upon examination there was found bilateral laceration of cervix, the cervical mucous membrane congested, relaxed, and everted. Uterus measured three inches. Perineum ruptured to the sphincter, with tendency to rectocele and cystocele.

November 22d. After a fortnight's preparatory treatment by hot douches, laxatives, etc., she was etherized, the cicatricial tissue thoroughly removed from both lips, and the surfaces drawn together by half a dozen wire sutures.

November 30th. Has had carbolized douches and an enema daily. One suture removed from each angle.

December 5d. Four remaining sutures removed.

December 8th. Union perfect. Was sent out for ten days, preparatory to repair of perineum.

December 18th. Reports that she was taken unwell the day after leaving hospital, and that the flowing and pain were much less than before the operation. Has less pain in back, but still some dysuria. After a few days of rest and douching, on the 22d, the perineum was cleared of cicatricial tissue and closed in the usual way with wire sutures.

December 29th. Sutures removed. Perineal body well restored, but some gaping of the integuments to be restored by granulation.

January 15th. Discharged well, and directed to return later for a pessary should the retroversion recur.

A CASE OF SEVERE LARYNGEAL SPASM IN AN INFANT.¹

BY F. GORDON MORRILL, M. D.

THAT pressure upon the recurrent laryngeal nerve may produce severe and even fatal laryngeal spasm is a fact which has been repeatedly verified by autopsies. This pressure is generally due either to the presence of a malignant growth or an aneurism, and is of course far more likely to occur in adults than in children. Writers on children's diseases refer to spasmodic affections of the larynx as occurring in one of two forms: laryngismus stridulus (thymic asthma), or that far commoner form of spasm which so frequently accompanies ordinary catarrhal laryngitis. Neither Bouchut, Meigs and Pepper, J. Lewis Smith, West, or Steiner (in his *Compendium of Children's Diseases*) make any mention of enlarged cervical glands as a factor in the production of laryngeal dyspnoea, except to doubt their having any connection with laryngismus stridulus — called also child crowing or thymic asthma. The following case bears directly upon this point, as it proves the direct connection of pressure by enlarged glands with spasm of the glottis in its severest form.

January 24, 1880. I was asked to see an infant of nine months, whose previous history is as follows: —

From birth (although of fairly healthy parentage to all appearances) she has suffered the train of evils usually attributed to scrofula, including ulcerations of the cornea, ozæna, aphthous stomatitis, and enlarged cervical glands; and in spite of healthful surroundings and assiduous care her existence had thus far proved a struggle which seemed likely at any time to end unfavorably. During the four days preceding the date of this visit her symptoms had been those of catarrhal laryngitis — certainly nothing more.

I found the child's attendants in a state of terror and confusion, which her condition certainly appeared to warrant. She lay in her mother's arms, with her head thrown back, livid, and seemingly moribund. The respiration at times ceased entirely, and then recommenced with convulsive gasps, ending in a deep breath, drawn evidently with the greatest difficulty. The symptoms were far more intense than anything I had ever seen. The pulse could not be felt, and as the intervals between the respirations grew longer and the breaths themselves shorter the situation became ex-

treinely unpleasant. On each side of the neck there were swellings composed of groups of enlarged glands, which had existed some days, but had given no evidence of fluctuation, and were still perfectly firm to the touch. Having no bistoury with me, I hastily made quite a deep incision in the more prominent swelling (that on the left side) with a pen-knife, but was disappointed in seeing nothing but blood, and that in considerable quantity, flow from the cut. After a little probing with a hair-pin, however, a discharge of pus ensued, which may have amounted to a teaspoonful, and was followed immediately by a marked change for the better in the child's symptoms, — the respiration at once becoming regular, and the patient going quietly to sleep after taking a little rum in milk. Two days later the same performance was repeated, and opening the swelling in the opposite side of the neck had an equally good effect. Since that time no enlarged glands have been discovered, and the child has had no respiratory trouble of any kind.

I think under the circumstances we are justified in regarding pressure by the enlarged glands upon the recurrent laryngeal nerve as the immediate cause of the spasm; and I see no reason why pressure of this kind should differ in its effects from that caused by malignant growths or aneurisms, both admitted factors in the production of fatal laryngeal dyspnoea. In an adult the same degree of spasm would have probably occasioned much less trouble, as the soft and fibrous texture of the infantile larynx renders atmospheric pressure an important factor in narrowing the opening of the glottis during inspiration, whenever spasm of the tensors is present to hinder the free entrance of air. The child's immediate recovery in both instances from symptoms which I feel sure would have speedily led to death proves (at least to my mind) that the case was one of spasmodic contraction of the tensors, from interference with the filaments of the recurrent nerve which supply these muscles, and not one of paralysis. If the latter had been present, atmospheric pressure would have speedily closed the glottis, and nothing short of tracheotomy would have afforded relief. In adults, on the other hand, the presence of paralysis (unless of both abductors only) would still have admitted of respiration being performed, owing to the cadaveric position assumed by the affected muscles, the wider aperture of the glottis, and its firmer texture offering the necessary resistance to atmospheric pressure. The only case I have been able to find record of in which enlarged cervical glands play an important part in causing laryngeal troubles is given in Morell Mackenzie's work (London, 1880). Here a case is related in which there was complete anesthesia of the interior of the larynx and paralysis of the thyro-epiglottic, ary-epiglottic, and crico-thyroid muscles, causing the epiglottis to maintain the erect position, and rendering the cords lax when adducted. Here the trouble was due to a mass of enlarged glands pressing upon the superior laryngeal nerve on one side, and pressure upon the corresponding nerve of the opposite side by a post-pharyngeal abscess besides enlarged glands. In a short time the abscess discharged, the glandular enlargement subsided, and all symptoms promptly vanished. The case which forms the subject of this paper, occurring in so young a child and being so plainly due to the pressure caused by enlarged glands, is unique, so far as I have been able to discover by tolerably careful reference to the literature of the subject.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

FEBRUARY 14, 1881. DR. T. B. CURTIS in the chair.

DR. JAMES J. PUTNAM read a paper on the Diagnosis of Locomotor Ataxia in the Early Stages.¹

DR. WEBBER said he was very much interested in Dr. Putnam's excellent paper. He agreed with the author as to the necessity for the strict cross-questioning of patients when there is any suspicion of locomotor ataxia. The earlier symptoms are usually looked upon as unimportant by the patient, and, being more or less remittent, their value is not appreciated, also many times the patient's memory is at fault, so it is well to ask a question, then turn to other points in the history, and return again to the original question.

Dr. Putnam seemed to give rather more prominence to the pains about the head than Dr. Webber's experience would justify; these are very rare, quite exceptional. It needs, also, to be remembered that the various visceral pains, the crises, so called, are rare. They are, undoubtedly, of the same nature with the pains in the legs and elsewhere. Physicians do well to bear in mind that it is only by studying the combination of symptoms that a diagnosis can be made, often only by exclusion. No one symptom is pathognomonic; any may be wanting in a given case. In two cases seen by Dr. Webber the pains were wanting; one of these developed into well-marked ataxia, the other, after the appearance of the first symptoms referable to sensational anesthesia, advanced rapidly to ataxia. It is not unlikely the disease had existed in a latent form in the cord, giving rise to no suspicious symptoms during several years. The patient had been married many years, a dozen or more, and had indulged in coitus, as a rule, every night during that time. He had no pains; dying from other causes the cord was examined, and showed the characteristic changes of locomotor ataxia. In another case with optic atrophy and severe pains with other symptoms tendon reflex was not lost. This patient has done well under treatment, and the disease seems to be at a stand-still. It would be interesting to inquire in other cases whether retained tendon reflex can be looked upon as giving grounds for comparatively a favorable prognosis.

As to treatment, nitrate of silver has been of service in Dr. Webber's practice several times, the pain being diminished, and in some cases there being apparent improvement in the gait. Galvanization of the spine has also been of value. It is not easy, however, to judge of the value of remedies in a disease which so frequently has remissions.

DR. MINOT had been called to give an opinion in the case of a patient who had lately noticed a good deal of irritability of the bladder, followed by difficulty in walking in the dark or even in the twilight, so that he did not dare to go out of the house after sunset, for fear of stumbling. These symptoms had been noticed only a short time before the beginning of the disease for which advice was sought—a rapidly developed pulmonary consumption, which proved fatal shortly

afterwards. No doubt if the patient had lived the spinal disease would have developed itself afterwards. In another case, which was under observation for several years, there were deformities in both shoulders, elbows, and wrists, the joints being nearly dislocated. From time to time there would be an attack of pain in the part, followed by much swelling; this would partially subside, leaving the deformity a little worse than before.

DR. WADSWORTH said: Within the last year or two a number of cases have been reported in which the diagnosis of locomotor ataxia has been made from the symptoms of optic nerve atrophy and absence of patella tendon reflex alone, and in a recent paper Hughlings Jackson believed himself justified to make a positive diagnosis of locomotor ataxia from a paralysis of some of the ocular muscles supplied by the third nerve, and absence of the tendon reflex, the patient presenting no other symptom of the disease.

There is a possibility, however, that one may go too far in this direction. I say this not to depreciate the value of the absence of the tendon reflex as a symptom, on the contrary I regard it as an extremely valuable one, but in some cases, unless very great care and caution are exercised the reflex may seem to be absent when it is not. This is a mistake which I have made once myself, and which I have seen made by others. So, also, the proportion of cases of simple atrophy of the optic nerve in which evidences of locomotor ataxia developed later has been shown in the last ten years to be much greater than was formerly believed. In one of my patients, referred to by Dr. Putnam, I found optic nerve atrophy, in 1873, and symptoms of it had existed a year or two earlier, but it is only within about a year that other symptoms of locomotor ataxia have shown themselves. Gowers observed a case in which optic nerve atrophy preceded by twenty years the other symptoms.

I think Dr. Putnam is in error in stating that the idea of an atrophy of the optic nerve from the abuse of alcohol and tobacco is not generally received by ophthalmologists. There are many who do not go so far as Hutchinson in believing that the abuse of tobacco alone is the cause in so large a proportion of cases, but that abuse of tobacco or alcohol, or of both together, not very infrequently produces atrophy of the optic nerve is generally accepted. There are, however, some clinical differences between the course of this affection and that of progressive atrophy from tabes dorsalis. In the atrophy from abuse contraction of the field of vision does not, as a rule, occur so early, and there is generally a partial central scotoma, which may be detected only by central absence of perception of colors, especially green and rose.

DR. WEBBER said, when we consider the causes of the disease—excessive exercise, excess in venery, exposure of feet and legs to wet and cold, etc., and the necessity that patients with the earlier symptoms should avoid all such causes, it may be the physician's duty to tell the patient frankly from what disease he is probably suffering, and so give him to understand the great importance that he should assist by avoiding all such injurious influences. A patient who has been thus warned will be much more likely to follow the directions.

DR. ELLIS inquired whether the earlier symptoms of ataxia can be recognized with enough certainty to render it advisable to make a definite diagnosis. He also mentioned a case seen by him in 1878 with Dr. Curtis,

¹ Vide page 169 of this JOURNAL.

where there was urinary difficulty and pain but no ataxia, and where, in the spring of 1880, marked symptoms of ataxia appeared.

DR. T. B. CURTIS remarked that, according to Vulpian, gastric paroxysms were occasionally met with in which only fits of vomiting occurred, with little or no gastric pain. Another form of the "visceral crises," first described by Dr. Maurice Raynaud, of Paris, consists in paroxysms of renal pain, simulating kidney-colic of calculous origin. With regard to the palliation of the acute and distressing paroxysmal neuralgic of tabes, a very simple and harmless means of relief, first adopted by Professor Potain, of Paris, and eulogized by Vulpian and by Dieulafoy, consists in subcutaneous injections of pure water, of which eight or ten drops are injected rather deeply *in loco dolenti*. This unobjectionable remedy is said to be often efficacious against other kinds of pain, such as that attending rheumatic arthritis, myalgia, or the idiopathic neuralgia.

Dr. Curtis remembered well the case alluded to by Dr. Ellis. Paroxysms of vesical pain, with tenesmus and incontinence of urine, were the symptoms chiefly complained of by the patient. A careful exploration showed the absence of stone, as also of stricture and of any organic disease accounting for the functional disturbances. There was a slight catarrh of the bladder, insufficient, however, to cause the acute suffering occasionally experienced. On cross-examination of the patient with reference to his past history and other symptoms, he was found to have suffered for upwards of five years from typical lightning pains, boring and lancinating, which first affected the heel; vertigo had existed for three years; he had also suffered from attacks of *proctalgia*, or rectal pain and tenesmus. A characteristic tottering gait has lately confirmed the diagnosis made three years ago.

One last point Dr. Curtis wished to touch upon: venereal excesses figure prominently in the accepted ætiology of tabes, being a common antecedent of the characteristic and conspicuous locomotor disturbances; he would, however, inquire of Dr. Putnam whether sexual excitement was not one of the early symptoms of tabes, and whether sexual excesses ought not to be considered rather a result than a cause of the disease?

RUPTURE OF BLADDER BY EXTERNAL VIOLENCE.

DR. F. W. DRAPER presented the pelvic organs from the body of a woman, aged twenty-eight, who, five days before her death, had fallen down stairs while intoxicated. Her symptoms after the accident had been great pain in the abdomen, retention of urine, frequent desire to micturate, hæmaturia, vomiting, extreme prostration.

The autopsy disclosed a rupture of the bladder, the rent being crescent-shaped, situated in the posterior wall to the right of the middle line and measuring two inches in length; its edges were quite symmetrical; its direction was from below upward, its upper end being near the fundus; it involved the entire thickness of the posterior wall, the fissure being of equal length externally and internally. Through this opening the urine had escaped freely into the adjacent tissues in all directions, infiltrating the connective tissue in front as far as the umbilicus, behind as far as the diaphragm, and downward into the deepest parts of the pelvis; the infiltrated tissues were shreddy, gangrenous, and of a strong urinous odor. There was no peritonitis, the escaping urine having invaded the subperitoneal regions

only. The mucous membrane of the bladder presented many patches and small points, slightly raised, having a bright red base and a slaty-gray exudation at their summit (diphtheritic cystitis).

MUMPS; ORCHITIS.

DR. MINOT reported a case of orchitis following an attack of mumps in a delicate man thirty years of age. The patient had had mumps before. He was confined to the house for a few days with this attack of mumps, and then began to have a feeling of uneasiness in the testicle which, in a few days became swollen, but was not tender.

DR. HODGES remarked that the swelled testicle following mumps was always a much lighter affair than that occurring in gonorrhœa.

MEASLES.

DR. J. AYER reported a case of measles, unlike any which had ever occurred in his experience before.

In January he was called to the elder of two little sisters, eight years old, having well marked symptoms of measles, namely, catarrhal fever, cough, and eruption on face and chest.

Twelve days later he visited same patient again. In the interval the younger sister, six years old, had passed through a smart attack of measles, and had almost recovered. This patient (the elder girl) was feverish. Thermometer 103° F., nausea and cough, the next day all the early symptoms of measles were apparent. The eruption was perfect and the affection ran its usual course, confining the patient for three or four days. Both children made a slow recovery, with abundant desquamation.

In Ziemssen the name relapsing measles is applied to this class of cases.

Van Diesen reports a girl three years old attacked by measles in February, 1848, and recovering; again attacked March 4th with preliminary symptoms and exanthemata; had another attack with all the symptoms, April 12th. The three attacks were succeeded by branny desquamation.

DR. GOSS spoke of a case of measles where there was an undoubted recurrence of the disease within three weeks after the first attack.

DR. WHITE reported a case where it occurred twice in eight days.

DR. WADSWORTH one which recurred in three weeks.

DR. WEBBER reported a case of German measles where the enlarged glands appeared six or seven days before the eruption. The incubation in this case was estimated to be from seven to ten days.

DR. F. C. SHATTUCK asked why Dr. Webber applied the term *German* measles to his case. There is at present an epidemic of genuine measles in this city, an epidemic which is remarkable in this particular, namely, its mildness and the frequency with which both adults and young people who have already had the disease once are again attacked. Cases of measles vary greatly in severity and in the completeness with which the symptoms and complications are represented, just as do cases of scarlet fever or any other disease. During the prevalence of an epidemic of measles it would seem safer to be very guarded in the use of the term *German* measles, by which is denoted an affection resembling measles, and yet, according to Thomas, the writer of the article *Rötheln* in Ziemssen's *Cyclopædia*, and others, entirely distinct from it.

PROCEEDINGS OF THE BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

MEETING OF NOVEMBER, 1880. DR. J. B. AYER read a paper on

ALCOHOLIC MANIA IN CONNECTION WITH ACUTE DISEASE,

of which the following is a synopsis:—

According to Dr. Greenfield, the translator of Magnan's work on Alcoholism, there are few medical subjects upon which less has been written than upon acute and chronic alcoholism. The very frequency of the alcoholic element in disease has caused the subject to be neglected.

Verneuil's paper Upon the Prognosis of Injuries and Surgical Operations in Drunkards, in December, 1870, awakened much interest among the profession. He stated that the deplorable state of the system engendered by alcohol was as important a cause of failure in surgery as exposure to morbid germs. He proved that habitual drinkers who had previously never seemed the worse for liquor often developed the most serious complications, after receiving insignificant wounds.

He urged that alcoholism, as it so frequently complicates disease, should be studied by the physician no less than by the surgeon.

According to Magnan the habitual drinker ceases to enjoy immunity as soon as the physiological equilibrium is destroyed by the blow of an intercurrent disease.

The following is a summary of a case cited in illustration:—

The patient, fifty-one years of age, had for the past thirty years stimulated freely without apparent injury to himself, as he always seemed to enjoy the best of health.

The day following more than usual indulgence he was attacked with a catarrhal cold and severe lumbal-abdominal neuralgia. There was nothing unusual about the case until the sixth day, when the fever, pain, and jaundice having disappeared he suddenly developed hallucinations of sight and hearing, and became very suspicious. At first he said little regarding the hallucinations, but as they increased he began to mention them freely, and argued that the pigmies and insects which he saw, and the voices which he heard, were all real, and insinuated that those who did not agree with him were stupid folk.

Muscular tremor, copious perspiration, insomnia, and loss of appetite were prominent symptoms.

On the third night after the disappearance of the catarrhal symptoms he was greatly excited fighting with his imaginary foes. But when he was at the worst he would answer a question correctly, his mind instantly reverting, however, to the old delusions.

On the fourth day, after consultation with Dr. Jelly, it was decided that full treatment must be carried out. He was accordingly removed to another room. Four doses of chloral and bromide of potash were given at intervals of about an hour up to seventy grains of chloral and eighty-seven grains of bromide, by which time the patient was well under the influence of treatment. Strong beef tea and egg-nogg were insisted upon. This treatment was not carried out without a great deal of urging.

After a two hour's nap the patient awoke with fewer

hallucinations. During the following twenty-four hours they gradually lost their hold upon him, and he slept a great portion of the time without further sedative treatment.

He was given ferro-phosphorated elixir of calisaya and the stimulant was gradually diminished to a little sherry wine and a glass of ale daily with his meals. Although he made a perfect recovery it was over three weeks before he could give close attention to business without bringing on headache.

While the insomnia, trembling, and free perspiration, in connection with the peculiarities of the hallucinations and the possibility of diverting the patient's attention from his delusions, pointed strongly to the alcoholic character of the delirium, yet a *positive* diagnosis could not at first be made.

A case was cited, which had been under the reader's care, of a young lady recovering from an attack of peritoneal cellulitis, who developed hallucinations about bugs, snakes, and Chinese pigmies, and in most respects resembled the previous case. The excitement, however, was not connected with alcoholism. She grew worse and was removed to the South Boston Lunatic Hospital, from which she was discharged well at the end of five months.

The reader advised caution in giving a prognosis in cases of alcoholism, agreeing with Lawson that "the intense furor accompanying alcoholic brain disorder may disappear under treatment in a single night, yet under precisely the same appreciable conditions the excitement in another case may continue for weeks, the delirium lasting as long as the deterioration of nutrition and the instability of nerve centres combine to maintain it."

Regarding treatment, bromide of potash and chloral, together with strong beef tea, broths, and (generally) egg-noggs, were advised. Balfour's treatment by forty grains of chloral every hour for three doses (for an adult), combined, if heart is feeble, with one half to one ounce of infusion of digitalis, was commended.

In the discussion which followed, DR. WEBBER said that it seemed to him, from the account of the case given by the reader, that the patient was really suffering from delirium tremens, not that it was a case of mania induced by an acute disease in a person addicted to hard drinking. The fact that the patient had been a very hard drinker, and had taken nothing for four or five days, and then was attacked with tremor, sleeplessness, hallucinations of sight and hearing, the objects seen being such as were described, resembling those seen in delirium tremens, renders it probable that that was the disease. The acute disease may, perhaps, have been one element in causing the attack, though the abstinence from alcohol was probably the more influential.

In comparatively mild cases of delirium tremens chloride and bromide of potassium are certainly beneficial. Small doses of these drugs, however, do no good; twenty, thirty, and even forty grains of chloral with thirty to sixty grains of bromide of potassium are more likely to be efficacious in procuring sleep and restoring the patient to sound mind than the smaller doses of ten to fifteen grains, which are sometimes given. The larger doses may be repeated hourly if necessary. One disadvantage of small doses is that the patient seems to be more excited after taking them, and finally a larger quantity of medicine is required.

In severe cases, where the pulse is rapid and feeble

120 or more), and where there is great excitement accompanied with hallucinations of sight and hearing. Dr. Webber stated that he had found digitalis the best remedy. He uses the tincture in very severe cases in doses of half an ounce, which may be repeated at the end of four hours if necessary. Many times one dose is sufficient to secure quiet; he has known patients who were greatly excited to fall asleep within half an hour after taking the drug. He would not advise the frequent repetition of these doses. In using digitalis it is all important to observe the pulse: where that is very rapid and feeble in uncomplicated cases large doses can be given; where the pulse is only moderately increased in frequency the larger doses are not called for, one or two drachms being sufficient. Where delirium tremens is complicated with other diseases which have either preceded the mania-a-potu or have occurred at the same time with it, as pneumonia or bronchitis following exposure while the patient was drunk, the treatment must be modified according to circumstances.

Delirium tremens usually occurs in old toppers or persons who have been addicted to the so-called moderate use, and have at length been on a spree of several days or weeks' duration. Besides the ingestion of alcohol there is usually also abstinence from food, the patients declaring that they have eaten scarcely any food for one or two weeks, or even longer. There is also usually insomnia, for a longer or a shorter time, and these elements undoubtedly play a part in the delirium tremens.

He said that during the war, in the latter part of 1862, he was stationed on board the receiving-ship Ohio as assistant surgeon; many men were enlisted in the navy who were received on board partially intoxicated, or who had but lately been drinking heavily for a long time; in several instances these men were taken down with delirium tremens after some days of enforced abstinence on board ship. This would show that, contrary to the opinion of some, the sudden breaking off of drinking may be one factor in causing the disease. Most of the patients, however, who are received into the hospital continue to drink up to the time of the attack.

In regard to treatment where there is vomiting, the tincture of capsicum in doses of half a drachm or a drachm is of value, and may be given in combination with the chloral and bromide. After the severity of the attack has passed off, while the patient is still weak and tremulous, three to five grains of quinine seems to be of use to restore the natural tone of the system.

Dr. GEORGE W. GAY then said, this affection is so common in the surgical department of this hospital that we are constantly on the watch for the tremulous tongue and hand, and any undue nervousness in our recent casualty cases. I have also noticed that the wounds of patients threatened with delirium tremens are sensitive out of all proportion to their severity.

Steady drinkers brought here on account of an injury are very apt to show signs of the horrors of delirium tremens, however slight the injury may be. The disease is usually developed in three or four days, and lasts from one to three days, sometimes longer; occasionally it terminates in chronic mania.

The most common treatment here is beef tea well seasoned with red pepper, given as freely as the patient can take it; chloral (fifteen to twenty grains), bromide of potash ammonia (thirty to forty grains), ev-

ery two or three hours; tincture digitalis in half-ounce doses where the heart is weak. I often preface the treatment with five grains of calomel and fifteen grains bicarbonate of soda. The great majority of cases recover.

Dr. ROWE referred to the well-known fact that patients who had previously received traumatic injuries to the head were peculiarly susceptible to much smaller quantities of alcohol than the ordinary patient. He cited within his knowledge several patients of this class at the Boston Lunatic Hospital who, by very moderate quantities of stimulants, had been made maniacal for varying periods. One case of delusional insanity, having a history of previous head injury, was made excited, sometimes, requiring seclusion, by so mild a stimulant as new cider, sometimes served at the social parties given to patients.

Dr. Ray has written a monograph on this feature of brain disease, which can be found in his Contributions to Mental Pathology.

Dr. ROWE, while physician at the House of Correction at South Boston, had tried nearly all reputed remedies in alcoholism, but found in the majority of cases that nothing served so well as moderately large doses of chloral and bromides. His experience with hyoscinamine had been of no avail, but deemed the particular samples used by him as not true hyoscinamine.

Dr. BANCROFT said: In reference to the aetiology of an attack of delirium tremens, two cases occurred under my observation at the City Hospital which seemed to show that the attack did not occur immediately after a prolonged spree, nor after the withdrawal of the daily quantum of liquor; but upon the indulgence in a single glass of whiskey after a total abstinence of four or five days. The patients were doing well, but after partaking of four or five ounces of liquor surreptitiously introduced by their relatives, they immediately developed violent attacks of delirium tremens, of which one of them died.

Dr. Bancroft described the case of a young man aged twenty-five, who has recently died at the New Hampshire Insane Asylum. The facts in brief are these: in the year 1877 he suddenly shot a man, without having given much evidence of approaching mental disturbance at that time. Was committed to jail, and during his first day's residence there broke out into a wild mania. His insanity being unquestionable, he was at once removed to the asylum. From the date of his committal, May 24, 1877, until October 12, 1880, he did not utter a single intelligible, connected sentence. He was in almost constant motion, tearing his clothes, filthy in the extreme, and requiring the continuous attention of the attendant. The incoherency of his speech was simply indescribable; one thought had scarcely any connection with another.

For three years he remained in this state. On the 12th of October, after a period of unusually wild excitement, the attendant entered his room and bade him "Good morning;" the patient turned about suddenly and said: "I want to die. I feel ready to die. I have suffered for three long years, and I want to go where I can rest." These were literally the first intelligent words the patient had uttered for three years. He repeated these words a number of times during the next few hours. But he seemed gradually sinking. Occasionally he rallied, and there seemed to be something on his mind that he wished to say. He did speak, among other things, of his wife and of trouble he had had

with her, and his daughter, giving the name and age of the latter.

When the attendant went out of the patient's room the latter would call him back, and say there was something he wanted to tell him, but he did not seem able to express himself.

He gradually failed, and died the following day.

MEETING OF DECEMBER, 1880. DR. CHANNING read a paper on

THE CARE OF INSANE CRIMINALS,

which is published in this number of the JOURNAL.

DR. T. W. FISHER spoke as follows: He agreed with most of the opinions and recommendations of the paper, and remarked that his acquaintance with the criminal insane at the House of Correction, at Deer Island, and elsewhere had been considerable. He had noticed a general reluctance on the part of all officials dealing with criminals to admit the existence of insanity except in marked cases. One reason was, he thought, that the criminal class generally showed characteristics which allied it closely with the insane class, and actual insanity was less conspicuous than in a perfectly sane community. Very many prisoners are deficient mentally and morally. Many are epileptic, and each one is under one delusion, namely, that of his own innocence of the crime for which he was committed. Impulsive outbreaks of unreasonable violence are common also to prisoners and to the insane. The habit of self-abuse is common to both, and also hallucinations of hearing due to chronic alcoholism. If an asylum for the criminal insane existed in this State, judges would feel less hesitancy in committing criminals suspected of insanity to it. Insane homicides are sometimes sent to prison for fear of an easy escape or discharge. Facilities for classifying the insane in asylums of different grades and of differing character are much needed in this State.

Recent Literature.

Clinical Lectures on the Physiological Pathology and Treatment of Syphilis, together with a fasciculus of class-room lessons, covering the initiatory period. By FESSENDEN S. OTIS, M. D., etc. New York: G. P. Putnam's Sons, 182 Fifth Avenue, 1881.

Some ten years ago the attention of the medical profession was first invited to Dr. Otis's views upon the "physiology of syphilitic infection," and they were noticed in this Journal of the date of May 30, 1872. Since that time Dr. Otis has published a series of papers upon this subject, which he now collates under the form of eight lectures, to which are added six class-room lessons, in a handsome, clearly printed volume of 116 pages, octavo, which we cordially recommend to every physician who regards medicine as a science rather than a trade. The reasoning is necessarily inferential, but also inductive; the arguments are based upon acknowledged features of syphilis in connection with the latest doctrines of the best pathological teachers; the evidences adduced are in favor of such views of syphilitic disease as are based upon purely scientific grounds, and tend to legitimately explain every phase of syphilis under its varied aspects, in complete accordance with known physiological and

pathological laws. Histology, the results of microscopical research, furnishes the groundwork of this volume, and several excellent illustrations are given from the works of various writers, together with a page of excerpts, embodying the views of recognized modern authorities concerning some of the properties and powers of embryonal or white blood cells.

Dr. Otis, as is well known, claims, with Bäumler,¹ that all the lesions of active syphilis have for their basis "cellular infiltration proceeding from the blood-vessels," and transmitted through the lymphatic system, and he now extends the same views over the later stages of syphilis, in accordance with the most recent advances in medical science. His treatment of the disease, in its different stages, is consequently considered in its relation to and based upon the rational or physiological view of the morbid processes involved. The first lecture treats of Beale's discovery of the living animal disease germ in various contagious diseases; of Biesiadecki's and Vernon's microscopic examinations of the initial lesion of syphilis, with their confirmation of Beale's views, and the arguments to show the probability of infection by such germs; of the reasons for supposing that such germs become incorporated with the white blood corpuscle; of the "necrobiosis" resulting from abnormal cell accumulation, which also accounts for "incubation" and the enlargement of glands. The second lecture substitutes the term "initiatory period" for "incubation" (so called), and shows that variations as to time and amount of induration are due to more or less superficial distribution of lymphatic vessels at the point of inoculation; that the disease germ affects only the white blood corpuscle; why the infection progresses slowly, and the propriety of including primary and secondary incubation under the initiatory period of syphilis. The third lecture considers the termination of the initiatory period, and the entrance of the degraded corpuscles — "carriers of the contagium" — into the general blood current, with roseola, coppery staining, "syphilitic fever," and general gland enlargement. The fourth explains inflammation of tonsils as resulting from their connection with the lymphatic system; so also a fourth variety of the initial lesion, papules, alopecia, mucous patches, syphilitic iritis, and the "gummy tumor of the iris," which is really a syphilitic papule, secondary pains in bones, nodes, and all eruptions, without exception, are shown to be dependent solely upon localized cell accumulation. The fifth regards all open lesions of syphilis as containing the contagious element, the contagious property not being a virus; the contagious property as ceasing with the active period of the disease; the late lesions as mere sequelæ, the "gummy material" consisting simply of normal germinal elements; fatty degeneration as due merely to pressure; late syphilis as the result of previous damage to lymphatic channels, and all forms of tertiary or quaternary lesions of syphilis as dependent upon a deposit of "gummy material" not due to the local action of a virus, but to the mechanical obstruction of lymphatic channels. The sixth holds that atrophy is from cicatricial contraction; gummy exudation the basis of cicatricial material, the deposit being identical with that due to ordinary pathological causes; fatty degeneration of brain tissue from accumulation of gummy material in the coats of arteries, as shown in Professor

¹ Ziemssen's Cyclopædia, vol. iii., pages 112 and 131, American edition.

Edes' case, and confirmed by Huebner's microscopical researches.

Lectures seven and eight are devoted to treatment. The virus of syphilis being an influence, and not a material substance, antidotes, as such, are merely the natural product of the supernatural view of syphilis. Mercury is the drug to be used, because its action is to disencumber the tissues from superfluous cell material, the product of a specific inflammation; not as an antidote to a hypothetical virus, but for the distinct scientific purpose of effecting the disintegration and elimination of the imperfectly organized cell elements which have been recognized as the cause of trouble, and tissue metamorphosis is essential to a cure. Every agent as yet proved beneficial in the treatment of syphilis is one which hastens this metamorphosis. Iodide of potassium is inferior to mercury. Iron must always be given, for mercury is not a tonic but a destructive agent, acting as a solvent of diseased material, and the highest type of treatment is to administer just that amount of mercury sufficient to destroy the diseased material without affecting the healthy cell and tissue elements. [Where possible, therefore, use direct local applications.—*Rer.*] Where mercury is not well borne use potassic iodide, which has but little curative influence in early syphilis, and insignificant power to prevent later lesions, but in the cure of the late lesions is of inestimable value, for the iodine compounds are potent agents in inducing fatty degeneration, the only method of removal of late lesions, just as mercury is the most potent agent in removing neoplastic growths. Combine the two, therefore, in the treatment of all the late lesions.

E. W.

A Text Book of the Physiological Chemistry of the Animal Body. By ARTHUR GAMGEE, M. D., F. R. S. London: Macmillan & Co. 1880.

In a recent lecture before the British Medical Association, Foster described the labor of the physiologist as a striving after an "understanding of the broader laws of that conflict of atoms which is going on in every tissue; that perpetual building up and breaking down; that molecular strife which appears now as the piling up of material in growth, now as the rush of a secretion, or the shock of a muscular spasm, or the thrill of a nervous impulse." The immensity of the field of labor thus indicated, the overwhelming details which beset it, and withal the intense fascination which illuminates every step of progress, may be surmised by a study of Dr. Gamgee's book, which we have just had the pleasure of reading.

This book deals only with the chemical characteristics of the elementary tissues, such as the connective, contractile, epithelial, and nervous tissues, including also the blood, lymph, and chyle. Nearly half the book is devoted to the blood in health and disease, and is evidently based upon original work as well as upon the best literature of the subject. Indeed, the author assures us that he has, "so far as possible, tried all the experimental processes mentioned in this work." The various stages of coagulation, and the numerous theories which have been advanced to explain that phenomenon, are presented in full detail and with greatest clearness. Chapter III. will prove, perhaps, the most interesting to the general practitioner, inasmuch as it recounts the changes of the blood in disease. In scarlet fever the author says there is primarily no al-

teration in the proportion of blood constituents. When kidney complications arise, however, there is a tendency to the accumulation of urea in the blood, and to a diminution of the proteids. The great increase of fibrine during diseases of the lungs and associate membranes may be seen from the following table:—

	1000 parts of blood yield	Fibrine. 2.5 grms.
In health,		
" bronchitis	" " " "	4.8 "
" acute pleurisy	" " " "	6.1 "
" " pneumonia	" " " "	7.4 "

The reason for this increase is hard to state, since we are ignorant of the origin of fibrinogen. In the proliferation of cellular elements which accompanies inflammation we have, however, an increase of the colorless cells and of serum-globulin, and according to Schmidt's theory these are the important factors in the manufacture of fibrine.

Chapter IV., with its elaborate description of methods, and bountiful illustration of instruments for analysis of blood, is a standing protest against the attempt to accumulate such valueless statistics as have been recently solicited by a circular, emanating from Washington, in reference to the condition of the blood in rheumatism. The circular named asks if rheumatic troubles are caused by an acid in the blood, and if this acid is uric. Without actual and laborious analysis of blood it would seem that any inferences regarding these points from merely "professional experience" would hardly be called "valuable" statistics. Dr. Gamgee distinctly asserts that rheumatism and so-called rheumatic gout are distinguished from true gout by the absence of any tendency toward the accumulation of uric acid in the blood.

Dr. Gamgee's book meets a want long felt in English medical literature, and should receive a warm welcome from the general practitioner as well as from the special student. It will well repay the time spent in reading it, and we are pleased to announce that the author promises us a second volume, within a year, which shall treat of processes characteristic of the more complex organs of the body.

February 15, 1881.

A Treatise on Diphtheria. By A. JACOBI, M. D., etc. New York: William Wood & Co. 1880.

The present book is given by the author to the public as an augmented edition of his monograph on the same subject which appeared in the second volume of Gerhardt's *Handbuch der Kinderkrankheiten*, 1877, with this exception, that it contains less literature and more therapeutics. His aim has been to give a condensed but tolerably extensive report on the present state of what is known about diphtheria, with his personal views on its pathology and treatment.

Dr. Jacobi considers the bacteria doctrine of diphtheria or the parasitic nature of the diphtheritic poison as not proven, and heartily embraces the results of the experiments of Drs. Wood and Formad on the effects of inoculating the lower animals with diphtheritic exudation, published in Supplement No. 7 of the National Board of Health Bulletin, as finally settling the mooted question of the essentiality of bacteria in regard to the nature and definition of diphtheria.

He thinks that the anatomical and clinical facts indicate that the contagious material of diphtheria is really of the nature of a septic poison, which is also locally very irritant to the mucous membrane, so that

when brought in contact with the mouth and nose it produces an intense inflammation without absorption by a local action. Whilst absorption is not necessary for the production of the angina, it is very possible that the poison may act locally after absorption by being carried in the blood to the mucous membrane. Further, under this theory it is possible that the poison of diphtheria may cause an angina which will remain a purely local disorder, no absorption occurring; or a simply local tracheitis produced by exposure to cold, or some other non-specific cause, may produce the septic material, when absorption will cause blood poisoning, the case ending as one of adynamic diphtheria.

We have reproduced this expression of the view, which the author is tempted to adopt, as bearing both upon the important and vexed questions of the identity and non-identity of croup and diphtheria, and upon the value of local treatment, such value depending largely upon whether the angina has or has not been preceded by absorption.

In the matter of treatment the author is opposed to the removal or destruction of local membranes, and lifts up a warning voice against the use of large doses of chlorate of potassium, the indiscriminate administration of which he believes to be responsible for grave renal complications, leading not seldom to death, the cause of which in such cases he thinks has been rarely suspected. Whether in regard to aetiology or treatment the book may be consulted by practitioners with advantage.

Photographic Illustrations of Cutaneous Syphilis. By GEORGE HENRY FOX, A. M., M. D., etc. Forty-Eight Plates from Life, colored by Hand. Complete in Twelve Numbers. New York: E. B. Treat, No. 757 Broadway. Nos. 4, 5, 6. Price \$2.00 per number.

We have received the fourth, fifth, and sixth fasciculi of Dr. Fox's excellent atlas of the syphilodermata of the skin. These colored artotypes not only hold their own, but are an improvement in several respects as to execution over those of previous numbers. In number four, for instance, we find two representations of papulo-pustular and pustular syphiloderms which are more natural than those in preceding fasciculi; another, quite life-like, of the corymbiform variety of pustular syphilis, and one of syphilitic onychia, showing well how the debilitating influence of the disease has interfered with the process of nutrition. The fifth number comprises a capital plate of plaques muqueuses or condylomata lata of the genital region (*S. papulosum humidorum*); two plates, each of two hands, of papulo-squamous syphilis upon the palms, the peripheral desquamation being admirably rendered; and, for purposes of differential diagnosis, one plate of Hydra [*pemphigus iris*], non-syphilitic, which will support our opinion that this fasciculus is, perhaps, the best one as yet issued of the series. Number six is composed of a squamous eczema of the palms for differential diagnosis, which is very well done; still too many plates for this purpose are hardly in place in an atlas devoted to representations of *syphilis*, since they are supplied by other atlases devoted to non-syphilitic diseases of the skin. Two circinate and one gyrate form of squamous, and one of ulcerative tuberculous, syphilis are well given, and will help to clear up many cases of very dubious diagnosis occurring in hospital wards. The final plate, *syph. tuberculosum*, is a clean cut picture of the mal-

ady in *stadio floritionis*. Two pages of text are added to each plate, speaking numerically, but the text is not explanatory in any way, and merely furnishes its quota towards completing the ranks, or chapters, of a volume upon syphilis in general.

Klein and Smith's Atlas of Histology. Part XIII. Philadelphia: J. B. Lippincott & Co. London: Smith, Elder & Co. 1880.

The closing number of this excellent work has reached us. It is worthy of its predecessors, and reflects great credit on all concerned in its production. It treats of the ear, the mucous membrane of the nose, the spleen and other so called ductless glands, and concludes with a very interesting chapter on the indirect division of the nucleus in epithelial cells. The direct division is the form generally known in which the nucleus is divided into two or more without undergoing any preliminary changes. In the indirect division remarkable changes in the intra-cellular fibrils occur, which we cannot discuss here.

We are now able to speak of the work as a whole. The illustrations are admirable, the text is good, and makes a symmetrical treatise of much value. There are two defects to which we believe we have already alluded, but we mention them once more in the hope that they may be removed from a future edition. The first is, that though the views of a great many abscesses are referred to we are not told where to find them. If abbreviated titles were printed in small type, this could be remedied without greatly increasing the size of the book. The other defect is a want of information as to the details of the methods by which such beautiful views were obtained. We do not ask for a treatise on technique, but for brief hints that would help those who are familiar with microscopical work. The book is so satisfactory as it is that we trust the authors will labor to make the next edition as nearly perfect as may be. T. D.

Differential Diagnosis. A Manual of the Comparative Semeiology of the More Important Diseases. By F. DE HAVILAND HALL, M. D., assistant physician to the Westminster Hospital, London. Second American edition. Extensive Additions. Edited by Frank Woodbury, M. D. Philadelphia: D. G. Brinton. 1881.

This book is founded upon Dr. Hall's synopsis of the disease of the larynx, lungs, and heart, the plan therein adopted being extended to embrace all the more frequent and important diseases. As in the previous edition preference has been properly given in most cases to American over European authorities. Dr. Frank Woodbury, the editor of the present edition, has revised the work thoroughly and added to it not a little. This revision has been carefully and judiciously performed. The book will be found handy and convenient for reference, whether by student or practitioner. For the student and young practitioner, unless possessed of unusual discrimination, we think synopses compressed into comparative tables of the clinical histories and leading phenomena of diseases are quite as apt to prove dangerous as useful. This is well illustrated in the table setting forth the differences between membranous croup and diphtheria. The statement that the contagion of measles is almost exclusively limited to children is in contrast with the late unusual experience with that disease in Boston.

Medical and Surgical Journal.

THURSDAY, FEBRUARY 24, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

REVACCINATION: A REPLY TO "DELTOID."

OUR readers have seen in the last number of the JOURNAL a communication signed "Deltoid,"—couched, let us remark, by the way, in unusually vigorous and athletic, not to say pugilistic, language, to which the writer's pseudonym seems not wholly inappropriate. Protest is therein made against certain statements contained in our recent editorial on small-pox and revaccination.¹ Deltoid refers to (what he is pleased to call) our "dogmatic statements concerning either prevention or cure, which rest on no more certain basis than the hobbies of their author." He then goes on to propound a series of questions touching the prevention of small-pox. These we will answer to the best of our ability, carefully dotting our i's, so as to try to preclude the possibility of any misunderstanding of our meaning.

We must, in the first place, admit that the necessity of repeated revaccinations is not *universally* recognized,—though unequivocally affirmed by Curschmann,²—nor was it our intention to advocate an indiscriminate or frequent repetition of thoroughly successful revaccinations. Deltoid's criticism of our statement touching this point is well founded, and we find ourselves constrained to recognize that he has, so to speak, "got in a blow on our nob," in fact, to carry out the metaphor irresistibly suggested by his spirited attack, we must grant him "first blood." It was not, however, any "hobby," but simply a perhaps somewhat unruly editorial pen, which, at this point, for a moment, got away with us. Fortunately, our error, or, rather, our over-statement, in regard to this accessory detail, is not likely to involve serious consequences if acted upon by any of our readers, for it errs, if at all, wholly on the side of safety and of superfluous precaution. To specify precisely the extent to which the practice of revaccination ought, in our opinion, to be carried, we cannot do better than to reproduce the precepts laid down by Seaton, which inculcate what may be said to be the minimum degree of prophylaxis consistent with safety: "From these considerations we draw the important practical rule that every person should take care to be revaccinated

about, or soon after, the period of puberty. Under ordinary circumstances, about fifteen years of age is the best time for it to be done, and it should not be left much beyond this, for the age of most danger from post-vaccinal small-pox is from fifteen to twenty-five. On the other hand, where there is any unusual risk of small-pox, as in localities in which the disease is prevailing, it would be imprudent to wait so long, and the revaccination may be done at any period after twelve years of age, or, in individual cases, even earlier than this. In girls, especially, in whom the changes connected with puberty manifest themselves early, revaccination may be performed correspondingly early. The degree, however, in which vaccinated persons, when they are grown up, stand in need of revaccination, is, I repeat, very different. Those who have imperfect marks need it much more than those whose marks are characteristic; those who have but one or two good marks much more than those with three or four. Small, indeed, as the risk of contracting the variolous infection in any form is to those who have been thoroughly vaccinated, who have four good marks of their vaccination, and infinitely small as is to them the risk of having it severely, it is a risk not worth the running, and as no individual can tell whether he is one of the wholly protected majority or one of the partially protected minority, it is the part of wisdom even for the best vaccinated to seek the additional security of a revaccination."³

In answer to Deltoid's inquiry for statistical evidence bearing upon the utility of revaccination, the following statements and facts may be cited from the authority already quoted. Seaton says that "after effectual *revaccination*, small-pox, even in its most modified form, is found very rarely, or scarcely ever, to occur. Thus, Heim found that in five years there occurred among 14,384 revaccinated soldiers in Württemberg only one instance of varioloid, and among 30,000 revaccinated persons in civil practice only two cases of varioloid, though during these years small-pox had prevailed in 344 localities, producing 1674 cases of modified or unmodified small-pox among the not revaccinated, and in part not vaccinated, population of 383,298 persons in those places in which it had prevailed. In the Prussian army, since the introduction of systematic revaccination of all, the annual deaths from small-pox, (which at one time were 104) have not averaged more than two; and on analysis of 40 fatal cases that occurred in twenty years, it appeared that only four were in persons who were said to have been successfully revaccinated. Other national experience might be referred to, but it will be better to have recourse once more to Mr. Marson's very precise statements. In the thirty-two years and upwards, that he has been connected with the small-pox hospital, no nurse or servant has taken small-pox, he having taken care always to revaccinate them on their coming to live in the hospital; and at a time when a large number of work-people were employed for several months about the hospital, most of whom consented to be revaccinated,

¹ See the JOURNAL, February 10, 1881.

² Curschman says: "In general, the duration of immunity may be stated at from eight to ten or twelve years. In order to maintain a state of perfect immunity after this period a revaccination is required, and this should then be repeated at every expiration of the above-mentioned period throughout the remainder of life." Ziemssen's Cyclopædia of Medicine. American Translation, New York, 1875, vol. ii., p. 406.

³ A handbook of vaccination, by E. C. Seaton, London, 1868, page 274.

two only were attacked by small-pox, and these two were amongst the few who were not revaccinated."¹

Deltoid inquires how the *Lancet* can know that "an effective revaccination is a better protection than small-pox itself." The superiority of the protection afforded by vaccination — and, *a fortiori*, by revaccination — over that accruing from antecedent small-pox is made manifest by the experience of the London Small-pox Hospital, based upon nearly five thousand "post-vaccinal" cases among others. Marson showed that, whereas the average mortality of post-vaccinal small-pox was five or six per cent., that of second attacks of small-pox was as high as nineteen per cent. Marson's statistical table² is so curious and instructive that we are tempted to take this opportunity to lay it before our readers:—

Classification of Patients affected with Small-pox.	Number of Deaths per cent. in each class respectively.
1. Unvaccinated	35
2. Stated to have been vaccinated, but having no cicatrix	23.57
3. Vaccinated:—	
a. Having one vaccine cicatrix	7.73
b. Having two vaccine cicatrices	4.70
c. Having three vaccine cicatrices	1.95
d. Having four or more vaccine cicatrices	0.55
e. Having well-marked cicatrices	2.52
f. Having badly-marked cicatrices	8.82
4. Having previously had small-pox	19

Deltoid says ironically: "You seemed filled with holy horror at the ignorance and inertness of those who do not share your apprehensions." Our holy horror—we consent so to call it—was excited not so much by the merely intellectual shortcomings alluded to, as by the many unnecessary and *preventable* deaths of grown-up persons—close upon five hundred individuals aged fifteen years and over having died of small-pox in Boston in 1872—shown by the vital statistics of the city to have taken place in the last epidemic.

One last point, not touched upon by Deltoid, seems to call for a few remarks. Many practitioners, although recognizing the utility of at least one revaccination, nevertheless advise their patients to postpone having recourse to this valuable means of prevention *until small-pox is already among us*. Seaton, however, who is the acknowledged authority on everything connected with the practice of vaccination, says explicitly, and shows, that "the performance of revaccination should not be left to periods when small-pox is epidemic." He says that "revaccination should always be done by preference when it can be done leisurely, and as part of the ordinary work of vaccination, and not under the alarm and influence of panic. . . . Under these circumstances, the demand for revaccination often becomes so great that it is difficult to find lymph to meet it. I have known revaccination-lymph used under these circumstances for performing other revaccinations, and very bad arms resulting."³

Such are the views we would advocate touching the practice of revaccination. In conclusion, we must

thank Deltoid for having afforded us an opportunity to define more precisely to our readers what we consider the *indispensable* exigencies of successful prophylaxis against small-pox; and we will also tender him our apologies for having, unwittingly, so disturbed his equanimity. And now, we trust that, divesting himself of his boxing-gloves, which, by the way, have seemed to us a little in want of *stuffing*, he will consent to go out of training, and to take the rest he has so well earned.

THE ACCURACY OF CLINICAL THERMOMETERS.

As long ago as 1754 the use of the thermometer, as an accurate measure of the temperature of the body in disease, was taught in Vienna by Antonius de Haen. It has, however, become indispensable to every medical man only within a few years. It is now a part of the armamentarium of every physician, and one of the earliest clinical lessons of the medical student relates to its proper use. It is as necessary in the proper appreciation of temperature as the watch in the account of the rapidity of the heart beat.

An article of such importance should be truly an "instrument of precision;" that it is not always so every one who has had occasion to compare different thermometers well knows, and to obtain accurate instruments physicians have been desirous of procuring thermometers of well-known English makers, as offering greater assurance of reliability than those of other less-known manufacturers. Much of the reliability of English thermometers has been due to the influence of the Kew Observatory, whose principal work, for the last quarter of a century, has been to furnish accurate comparisons of thermometers sent there by scientific men and instrument-makers. But even the best of thermometers are liable to change with the lapse of time, and to properly test them has been a matter of difficulty in this country. To meet this want, the Winchester Observatory of Yale College has established a Thermometric Bureau, which has been previously noticed in this and other journals. The habit of precise thermometric observation and record is so important that it has seemed expedient to the officials of the observatory to again call the attention of the profession to the errors to which clinical thermometers are liable, and the great difficulty of detecting them except with the appliances of an observatory devoted to this work.

The records of the observatory show that the clinical thermometers in common use cannot be relied upon within half a degree, and among those sent for comparison many vary more than this; a few have been received with an error of an even five degrees. Some of these inaccuracies are unavoidable; some are due to too great a desire to economize time, material, and skilled labor. Among the causes of error are enumerated the following:—

"(1.) The graduation is sometimes started from one point of the scale, near the normal, and the size of the capillary tube is guessed at. No upper point

¹ Beynold's System of Medicine, Philadelphia, 1879, vol. i, p. 175.

² Seaton's Handbook of Vaccination, page 216.

³ Beynold's System of Medicine, vol. i, p. 175.

being fixed by the maker, the higher graduations may be erroneous to the extent of several degrees. (2.) Too much air separating the index from the column of mercury causes the index to rise with a jerky motion; air above the index forces the index down when the thermometer is taken away from the body. In some thermometers, errors from this cause amount to two degrees at high temperatures. (3.) New thermometers increase their readings rapidly during the first months after manufacture, so that instruments which were right when made may change their indications as much as two degrees within a year.

"It will be seen that these errors are not such as the dealer can readily detect. Even in those cases where a dealer is provided with a standard thermometer with which comparisons could be made, it is a difficult matter to determine the errors of the standard itself, and the unsupported representations of dealers and druggists therefore, though made in perfectly good faith, cannot, from the nature of the case, afford the physician satisfactory evidence that any thermometer he may buy is not affected with errors, which in many instances under our observation have amounted to several degrees."

There is no desire on the part of the astronomer in charge to do injustice in these representations to the makers, who are generally willing to take advantage of the opportunities offered. Mr. Waldo expressly stated some time since that more accurate instruments were already being made under the encouragement of the observatory. It is, however, desirable to disseminate as widely as possible a knowledge of the work undertaken at New Haven, and of its necessity.

In commenting upon the matter, Mr. Casella, so widely known in connection with the thermometers which bear his name, says, "I am most glad to find that our American friends are adopting the Kew method of verifying thermometers for public use. This is clearly a step in the right direction, and well accords with the ability and devotion I have invariably found amongst scientific men of their country." Undoubtedly, the market will soon be supplied with thermometers with the Yale certificates. Physicians can at any time have their own thermometers tested for a small fee, and returned to them after three days with a certificate of their exact errors.

MEDICAL NOTES.

—The congressional appropriation committee have allowed but \$10,000 in the Sundry Civil Service Bill to print Volumes III. and IV. of the Index Catalogue. As it cost \$9000 for composition and stereotyping of Volume I. alone, it is evident that we must either do without Volumes III and IV., or else a more suitable appropriation must be made.

—Of the boys who were applicants for enlistment as apprentices in the United States navy during the year 1879, twenty per thousand were rejected on account of venereal diseases, twelve of these being syphilitics.

—As an instructive and somewhat amusing illus-

tration of the lay frame of mind concerning small-pox in the country, which has given us Jenner and vaccination, we reproduce the following:—

"The vaccination officer of Bethnal Green has asked his Board of Guardians for assistance to make a house-to-house visitation of his district, small-pox being still on the increase there. One member thought the request much too serious to settle off-hand, and that it should be referred to the dispensary committee. Another thought that this talk about small-pox was 'sheer nonsense.' The disease was 'simply nature righting herself.' A third thought twenty assistants would be needed to do the work thoroughly, which the vaccination officer wanted to be done (not seeing that the statement was a confession of the backward state of vaccination in the parish). A fourth thought that it would be unwise to employ such a large staff without due consideration.' So (the Local Government Board's advice, notwithstanding) the Board of Guardians will pause to consider a question which ought to have been 'considered' months ago, while small-pox steadily gains ground."

—In consequence of the recent fatal football accident in Southampton, the mayor of that town has issued a notice prohibiting the pastime on the public lands as long as it is played according to the Association or Rugby rules, and he calls on the heads of families and schools to support him in his endeavor to modify the practice of the game.

Apropos of this accident the *Lancet* gives expression to some sentiments, from which we quote, as of interest to the athlete at large:—

"There are many pastimes infinitely more ruinous to health than those we have enumerated. Dancing night after night in crowded, non-ventilated rooms is among the most unwholesome and dangerous practices of modern life, and kills infinitely more persons (though more indirectly) than either the 'Rugby' or the Association rules. The men who are killed by sitting in public houses, or (what is very much the same thing) in club houses, playing billiards or cards till the small hours, and drinking 'B. and S.' are not held up as warnings, while their fellows who happen to be killed while engaged in some sport which has in it a dash of nobility and pluck are spoken of as 'frightful examples' of the evils of this or that amusement. If by undue roughness or by unfairness one man kills another at a game, the ordinary law is sufficient to deal with him. This is enough protection, and we very much object to a return to anything approaching the sumptuary laws of a bygone age.

"The science of medicine has lately had its liberty seriously curtailed by sentimentalists. We shall very soon be restricted in our choice of diet by the followers of Sir Wilfrid Lawson. Only last session an absurd bill about acrobats met with a certain amount of favor in the House of Commons, and if a stand be not made our imperial vestryman, whose watchword—save the mark!—is 'liberty,' may be asked to regulate the method to be pursued in kicking a football, and impose a limit on the growing prowess of the rising generation."

— The following note we clip from the "trivial" columns of a daily contemporary : —

Anti-Vaccination societies will certainly preserve among their records the fate of the troupe of Esquimaux which Herr Hagenbeck has been conducting through Germany and France for the entertainment of the public. The poor creatures were very successful in Berlin, where Professor Virchow and others made them the subject of scientific examination. Thence they went to Darmstadt, where the most attractive member of the company died. In Westphalia two others died — a woman and a child, the latter of small-pox. From Crefeld they were taken to France, and at length the survivors, only five in number, reached Paris. There the sanitary authorities forbade Herr Hagenbeck to give a performance until the members of the troupe had been vaccinated. To make safety doubly sure the terrified Esquimaux were operated upon twice ; but, in spite of this extra precaution, they all fell sick and died of the small-pox within a few hours. This fact, of course, does not prove anything ; but those who are over-anxious to be convinced never require " confirmations strong as proofs of holy writ."

— In the *Annus Medicus* of the *Lancet* for December 25, 1880, under the section on therapeutics, we find the following : Not the least noticeable therapeutical communication of the year is that by Dr. Roderick Kennedy, of Kingston, Canada, on the use of large doses of olive oil for softening and causing the easy expulsion of biliary calculi ! In the review of surgery it is confessed that Chian turpentine has not realized the bright hopes at first held out. The writer yields himself somewhat prudently to a candid appreciation of litholapaxy, and says : In the surgery of the genito-urinary organs the year just closing has seen Bigelow's operation for stone in the bladder more firmly established. Increased experience has proved the truth of the chief of Bigelow's maxims, though most English surgeons have preferred not to follow their American *confrère* in his entire contention. The evidence now before the profession appears conclusive that lithotripsy with evacuation is far preferable to the older method of Civiale, although whether Bigelow has extended the limits within which the crushing operation is advisable is at present uncertain, such an astute surgeon as Cudge being of the opinion that he has not.

— We copy the following interesting note, The Antiquity of the Drainage-Tube, from the *British Medical Journal* : —

SIR, — The following passage from the Memoirs of Captain Creighton may be of interest to some of your readers. These memoirs were compiled by Dean Swift, from the manuscripts and oral relations of Creighton, who had been a " remarkable cavalier " in the reigns of Charles II. and James II., and were published in autobiographical form in the year 1731. In the skirmish at Ayrmoos, which took place in the year 1680 or 1681 (the old soldier is, unfortunately, somewhat careless about his dates), Creighton received a broadsword wound in the umbilical region, of which

he tells the subsequent history with some minuteness. I give his own, or rather the dean's, words, but abridge considerably : —

" My surgeon having neglected to tie a string to the tent of green cloth which he used for the wound, the tent slipped into my body, where it lay under my navel seven months and five days. When the tent was first missing, neither the surgeon nor anybody else ever imagined that it was lodged in my body, but supposed it to have slipped out of the wound while I slept. While I continued at Edinburgh, I ordered some pipes of lead to be made in a mould, through which the thin corruption which continually issued out of the wound might be conveyed as through a faucet. These pipes I cut shorter by degrees, in proportion as I imagined the wound was healing up at the bottom. When I was in Ireland, I made a coarse pipe myself. This pipe, after the wound was washed with brandy, always remained in my body till the next dressing ; but being made without art, and somewhat jagged at the end, it happened one morning, when the pipe was drawn out as usual in order to have the wound washed, the tent followed."

Are the rough-and-ready " pipes " of the shrewd old cavalier the first recorded instance of the drainage-tube ? Whether or not, he deserves credit for his ingenuity. I am, sir, your obedient servant,

CONOLLY NORMAN, F. R. C. S. I.

DISTRICT ASYLUM, MONAGHAN, IRELAND, December 15, 1880.

Miscellany.

A DISLOCATED KIDNEY WITH CYSTIC DEGENERATION.

MR. EDITOR, — The following case may prove of interest to your readers : R. S., a man about forty years of age, has been for some years past from time to time a patient of mine. I have attended him through several febrile attacks. Convalescence has been uniformly slow and tedious, he has complained much of a general malaise and has not had strength to perform manual labor, although a poor man dependent on his labor. It has seemed to me for years that some internal organ must be diseased, and yet there was no one group of symptoms by which I could satisfy myself as to the diagnosis. A year ago he had an attack of fever of about twenty-one days' duration. I discovered a hard bunch in the region of the stomach, which I thought, as did several physicians, would prove a schirrous stomach, though he lacked the general symptoms of that complaint. He recovered partially, but was feeble all summer. A short time since he died. At the post-mortem we found a tumor in the place of the stomach. There was no kidney on the left side. On the right side there was a tumor much resembling the other, only not as large. The liver and heart were somewhat enlarged. I weighed both kidneys, the one that occupied the place of the stomach weighed a little over two and one half pounds, and the one we found in place of the right kidney one and one half pounds. There was in both a mass of cartilaginous hardness, and a large number of small cysts, holding half an ounce of fluid which

looked like strong coffee or chocolate. I examined the urine frequently for the past two months, it was almost like clear water, some six or eight pints were passed daily, and the specific gravity at no time when I examined it was over 1005. There was not a trace of albumen or sugar, and it was deficient in the normal salts to a great extent. He had not complained to any extent of his kidneys, and did not suffer much from pain in any locality, though having a general discomfort. Very respectfully,

R. K. CLARK, M. D.
GEORGIA, VT.

RE-VACCINATION.

MR. EDITOR, — When a third-year medical student, in the winter of 1869-70, I visited a small-pox ward connected with the City Hospital. On, I think, two successive days I made the medical visit, and examined the patients in company with Dr. Webber, the attending physician. The four or five other students who made the visit at the same time were revaccinated immediately after. I carelessly neglected to take this precaution, relying upon the protection of a vaccination soon after birth and again in early childhood, leaving an interval of nearly twenty years since the revaccination. In due course of time I was taken down with a severe attack of varioloid, which kept me a prisoner for several weeks, and an ulcer of the cornea, developed during the progress of the disease, confined me to a dark room for several weeks after.

The inmates of my house were all revaccinated, and all escaped the disease, as did all my fellow students who had been exposed at the same time.

This is, to be sure, but a single case; but it was sufficient to convince me of the value of revaccination, as I feel sure I should have escaped had I taken equal precautions with my friends.

I shall be glad if it has any weight in influencing any one to take the same view as myself.

JAMES R. CHADWICK.

UTERINE DISEASES.

MR. EDITOR. — It is now perhaps two years since in your journal I read an account of *Viburnum prunifolium* being employed by some Boston physician in uterine diseases.¹ As many cases of diseases of women occurring in connection with nervous diseases are annually treated here, I desire to call attention to my own investigations with this comparatively new medicine. It appears to me to act directly and specifically upon the special nerves of the uterus as a true nerve sedative. I have had several very violent cases of congestive and neuralgic forms of dysmenorrhœa, in one case the dysmenorrhœa being accompanied by epileptiform convulsions of a very severe type, and in each and every case I have seen almost magical relief following the use of the fluid extract of *Viburnum prunifolium*. The case referred to, which was so severe that the intensity of the pain had worn out the unhappy sufferer and induced the epileptiform attacks, was completely cured in a few weeks by the combined use of the *Viburnum prunifolium* and the use of the constant current of electricity, the positive pole being applied to the hypogastric region, and the negative pole, to which was

attached a cup-shaped electrode, directly to the uterus. The galvanic current has a very powerful influence in suspending contractions of the uterus, and also is very efficacious, when used locally over the ovaries, in controlling ovarian neuralgia. Previous to my using the *Viburnum prunifolium* I had been accustomed to rely on valerianate of zinc and fluid extract of gelsemium with the constant current of electricity, but since my first experience with the former drug I have used nothing else. Although I have not had occasion to use it in cases of threatened abortion, I should deem it worthy of use from its action on the ganglionic nerves of the uterus. I have failed to perceive any action on the general system, the whole force of the medicine appearing to be directed to the uterus and its system of nerves. When the pulse has been high from nervous excitement, and the temperature centres in the brain have been temporarily paralyzed, allowing sudden rise in temperature, from nervous excitement, both pulse and temperature have fallen to the normal as the uterine pain has been relieved. It must be remembered, also, that my cases have been aggravated ones, many of my cases having been sent to Sunnyside on the verge of insanity. My conclusions, therefore, are, that in *Viburnum prunifolium* we have a uterine sedative more powerful than any other in controlling dysmenorrhœa and uterine contractions, and that it probably acts by passing from the blood to the nerve centres, and is special in its effect upon the ganglionic nerves of the uterus. Yours very respectfully,

EDWARD C. MANN, M. D.

SUNNYSIDE MEDICAL RETREAT,
TARRYTOWN-ON-THE-HUDSON, February 7, 1881.

"GEORGE ELIOT."

WITHOUT doubt, anything pertaining to the final illness of George Eliot will be of interest to our readers. We condense from the *London Lancet* the following account: —

On December 18th, "George Eliot" was present at an afternoon concert, which she much enjoyed. In the course of it her husband, Mr. John Cross, noticing that the place was somewhat draughty, proposed to throw her shawl over her shoulders: but she declined the attention, with the remark that it was very hot. On Sunday afternoon she felt a little chilly, but was well enough to receive and entertain Mr. Herbert Spencer and other friends. On Monday morning she was ill, and Mr. George Welland Mackenzie, summoned to see her, found her in a somewhat feverish condition, with symptoms of laryngeal catarrh. On Tuesday morning the laryngeal trouble had almost disappeared, but she complained of pain in the right lumbar and iliac regions, though not so severely as she had often felt it before. On Tuesday evening, although both laryngeal catarrh and lumbar pain were almost gone, her breathing was frequent, and she was restless and uneasy. The temperature, however, was not above 100° F., and a careful examination revealed no signs of fresh local mischief. On Wednesday morning there was considerable prostration; the breathing was hurried; the face was gray and anxious; and there was general uneasiness. Again Mr. Mackenzie made a careful examination without discovering any fresh local complication, which he was anticipating from the increasing gravity of the symptoms. On that evening,

¹ Vol. xlix., p. 634, 1878.

at six o'clock, Dr. Andrew Clark visited the patient with Mr. Mackenzie. A somewhat sudden and serious change had occurred in the course of the afternoon. The patient lay on her back, with the shoulders raised. The eyes were closed; the face was of an ashen-gray color; the lips were slightly livid; the arms lay extended on the coverlet; the breathing was extremely hurried, but quiet, and, on feeling the pulse, which was frequent, small, and irregular, the hand was found to be cold and clammy. On placing the stethoscope upon the chest, a loud to-and-fro friction was heard throughout the whole cardiac region. Death was evidently near at hand, and the heart rapidly failing; there was complete unconsciousness, and she ceased to live about ten o'clock.

Although the death of this illustrious woman appears to have been thus painfully sudden, it was not so in reality; preparation was being made for it during the last eight years. In 1873, on account of the cessation of a uric-acid deposit, and of attacks of pain in the right side and groin, Dr. Clark inferred the presence of a uric-acid calculus in the kidney. From that time until near the close of life there had been several attacks of pain, sometimes with and sometimes without hæmaturia. In the course of the year 1880 the urine had steadily fallen in density, and contained sometimes albumen, sometimes pus. In October last she was found to be suffering from symptoms of slight calculus pyelitis.

During the last few years, therefore, "George Eliot's" general health had been visibly failing. She was less capable of sustained work, and liable to sudden illnesses from small causes. The organism, well enough for the ordinary round of a quiet life, was unequal to any extra demand; and thus it was that a sudden chill brought it, unhappily, to a speedy end.

PILGRIMS AT MECCA.

According to the report of the Turco-Egyptian Sanitary Commissioners at Mecca, the number of Mohammedan pilgrims collected in and about the holy city (Mecca) during the pilgrimage just ended amounted, between the 3d and 16th November, to two hundred thousand persons; composed of natives of Turkey, India, Egypt, Morocco, Arabia, Syria, Persia, Java, etc. The greatest mortality amongst them after their first arrival in Mecca, about November 4th, was twenty-one daily. During the sacrifices on Mount Arafat the maximum mortality reached thirty-one daily, and in Mecca, after their sojourn on Mount Arafat it reached thirty-seven daily; the total deaths from November 4th to 19th being set down at two hundred and ninety-six.

The number of animals — sheep, camels, and other beasts of burden — collected in the neighborhood of the pilgrim encampment is estimated at a figure far exceeding the number of the pilgrims; and when we remember that this enormous host of people and animals are collected together in one vast encampment without any organized sanitary police to compel compliance with the orders of the sanitary authorities, the number of deaths is not surprising.

The same report states that during four days no less than a hundred thousand sheep were slaughtered in the valley of Mouna, and that, notwithstanding the establishment of thirteen slaughter-houses, fourteen

reaches for the interment of the carcasses of the slaughtered animals and the *débris*, five hundred and five public latrines, the sanitary authorities found themselves utterly unable to enforce their use for want of a proper sanitary police. — *Lancet*.

WANTON CRUELTY UNDER THE GUISE OF SPORT.

Is there any superfluous energy which is not worked off by associations like those for the Obstruction of Scientific Inquiry by the Suppression of Vivisection? If this is not the formal title of the organization it expresses the idea. A field admirably adapted for the exercise of pity and effective interference offers itself in connection with the monstrous pastime of pigeon-shooting. We have again and again called attention to these atrocities, committed under the pretence of "sport," and bringing unmerited contumely on the legitimate enterprise of the true sportsman, who would no more be guilty of pigeon-shooting *à la mode* than he would of chasing cats or flying cockchafers with pieces of cotton attached to their legs. There is a wondrous combination of brutality and imbecility in the slaughter of tame pigeons which makes the "amusement" difficult to describe. It has been asked whether a substitute could not be devised. A flight of toy boomerangs, or feathered tops, of the Lowther Arcade pattern, would afford fully as much diversion as the doomed consignment of pigeons sent to be slaughtered for the afternoon's entertainment of the women in satins and sealskins who frequent the places where this hideous cruelty is practiced. The only objection to substituting inanimate objects for the present victims would be that inasmuch as the feathered top and the toy boomerang would move, which the dazed and exhausted pigeons often refuse to do, the gallant sportsmen might find it difficult to make a decent score! There are, doubtless, devices by which a fair proportion of hits could be secured, but this we leave to the initiated. Suffice it, in the interests of humanity, as well of the suppression of cruelty to animals, to enter another protest against a practice which is nothing more or less than a wanton burlesque of sport. — *Lancet*.

ACCIDENT TRAPS.

WE referred last winter to one of the street dangers of which the gauntlet has to be run by pedestrians in frosty weather, namely, those horrible, shiny, intensely slippery, iron covers to the openings of street coal-cellers. Either in damp weather, or lightly covered with snow, these deceitful contrivances are a certain cause of accident to the unwary. A hundred times worse than a simple slide, they first cause the body to glide onward rapidly, and then, the foot arriving at the side, it is brought sharply up with a jerk, on the violence of which depends the amount of injury sustained by the unfortunate passenger. These slippery contrivances have during the past week been the cause of many broken limbs, and once more we protest against their use being any longer permitted. It is easy enough to substitute a roughened substance for the material they consist of — a measure imperatively called for in the interest of public safety. — *Medical Press and Circular*.

SUFFOLK DISTRICT MEDICAL SOCIETY.—A regular meeting will be held at the hall, 19 Boylston Place, on Saturday evening, February 26th, at seven and a half o'clock. The following papers will be presented: Dr. A. N. Blodgett, The Colloid Treatment of Strains and Sprains. Dr. B. O. Kinnear

will open the discussion. Dr. J. J. Putnam, A Case of Stretching of the Facial Nerve. Dr. S. G. Webber will open the discussion. Dr. E. W. Cushing will report Two Cases of Trephining. Supper at nine o'clock. All members of the Massachusetts Medical Society are invited to be present, and join in the discussion.
H. C. HAVEN, M. D., Secretary.

Deaths reported 2845 (no return from Buffalo); 1044 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 577, lung diseases 424, consumption 403, diphtheria and croup 216, scarlet fever 105, small-pox 64, diarrhoeal diseases 38, typhoid fever 29, erysipelas 28, cerebro-spinal meningitis 26, measles 23, malarial fevers 22, whooping-cough 19, puerperal fever seven. From *diarrhoeal diseases*, New York nine, New Orleans eight, Chicago six, District of Columbia four, Baltimore three, Philadelphia and Boston two, Brooklyn, St. Louis, Cincinnati, and Providence one. From *typhoid fever*, Philadelphia four, New York, Chicago, Boston, and Pittsburgh three, St. Louis two, Baltimore, Cincinnati, New Orleans, Milwaukee, Charleston, Lowell, Lynn, Holyoke, Gloucester, Haverhill, and Attleborough one. From *erysipelas*, Brooklyn six, Chicago five, New York and Philadelphia four, St. Louis and Cincinnati two, Baltimore, District of Columbia, Providence, Lowell, and Worcester one. From *cerebro-spinal meningitis*, New York, Chicago, and Lawrence five, St. Louis three, Philadelphia and New Orleans two, Charleston, Worcester, Fall River, and Brockton one. From *measles*, New York eight, Boston five, Chelsea three, Pittsburgh and Spencer two, St. Louis, Cambridge, and Newton one. From *malarial fevers*, New York 10, Brooklyn five, Chicago two, Boston, St. Louis, New Orleans, Milwaukee, and New Haven one. From *whooping-cough*, New York seven, Chicago, Boston, and Baltimore two,

Philadelphia, Brooklyn, St. Louis, Pittsburgh, Providence, and Lowell one. From *puerperal fever*, St. Louis four, Philadelphia, Newton, and Plymouth one.

Nineteen cases of small-pox were reported in Brooklyn; 14 in Chicago: diphtheria 38, scarlet fever four in Boston; varicella one, in Baltimore; small-pox four, in Pittsburgh; scarlet fever 43, diphtheria eight, in Milwaukee; measles 45, in Providence; diphtheria four, scarlet fever two, in Somerville.

In 43 cities and towns of Massachusetts, with a population of 1,118,958 (population of the State 1,783,086), the total death-rate for the week was 20.97 against 23.39, and 21.02 for the previous two weeks.

For the week ending January 22d, in 150 German cities and towns, with an estimated population of 7,806,891, the death-rate was 27.8. Deaths reported 4174; 1964 under five: pulmonary consumption 567, acute diseases of the respiratory organs 427, diphtheria and croup 197, scarlet fever 86, typhoid fever 67, whooping-cough 59, measles and röteln 38, puerperal fever 17, small-pox (Königsberg) four, typhus fever (Thorn, Frankfort-on-Oder) two. The death-rates ranged from 14.6 in Mannheim to 38.1 in Krefeld; Königsberg 33.6; Breslau 34.1; Munich 29.1; Dresden 24.1; Berlin 26.7; Leipzig 22; Hanburg 27.8; Hannover 18.7; Bremen 17.6; Cologne 24.8; Frankfurt 19; Strasburg 33.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 11, 1881, TO FEBRUARY 19, 1881.

BAILY, E. I., lieutenant-colonel and surgeon. The leave of absence granted him December 30, 1880, from A. G. O., extended one month. S. O. 35, A. G. O., February 11, 1881.

GIBSON, J. R., major and surgeon. To accompany Battery A (light) and Battery D, Second Artillery, from Fort McHenry, Md., to the U. S. Barracks, Washington, D. C., for temporary duty thereat. S. O. 26, Department of the East, February 11, 1881.

LIPPINCOTT, H., captain and assistant surgeon. Upon expiration of present leave of absence to report in person to commanding general, Department of the Platte, for assignment to duty. S. O. 34, A. G. O., February 10, 1881.

ELBREY, F. W., captain and assistant surgeon. Relieved from duty at Fort Bayard, N. M., and assigned to duty at Fort Union, N. M., relieving Assistant Surgeon Kane. S. O. 31, Department of the Missouri, February 12, 1881.

BYRNE, C. B., captain and assistant surgeon. To accompany Battery C, Second Artillery, from Fort Johnston, N. C., — abandoned, — to Washington, D. C., and then proceed to Fort Barrancas, Fla., and report to the commanding officer of that post for duty. S. O. 11, Department of the South, February 11, 1881.

HOFF, J. V. R., captain and assistant surgeon. To accompany the four batteries of artillery from Fort Monroe, Va., as medical officer, to Washington, D. C. S. O. 27, Department of the East, February 11, 1881.

FINLEY, J. A., captain and assistant surgeon. To accompany the battalion, Third Artillery, from New York harbor, as medical officer, to the U. S. Barracks, Washington, D. C. S. O. 27, Department of the East, February 11, 1881.

GARDNER, J. de B. W., captain and assistant surgeon. Relieved from duty in Department of Arizona, to proceed to Baltimore, Md., and on arrival report by letter to the surgeon-general. S. O. 34, C. S., A. G. O.

KANE, J. J., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon Elbrey to proceed to, and report for duty at, Fort Bayard, N. M. S. O. 31, C. S., Department of Missouri.

CORRECTION.

MR. EDITOR, — I hasten to correct a most strange error that has occurred in the report of the late councilors' meeting. I never said or thought that the "committee on membership" of the Massachusetts Medical Society had a right "to expel a man from the society." The society alone can "expel a man."

Yours truly, HENRY I. BOWDITCH.

Boston, February 17, 1881.

GYNECOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the society will be held at Medical Library Rooms, on the first Thursday of March, at 10:30 A. M. Subject, Pelvic

Hæmatoecle, introduced by a paper by H. B. Stoddard, M. D. Profession invited. HENRY M. FIELD, M. D., Secretary.

PERNICIOUS INTERMITTENTS.¹

DELIVERED IN CHICAGO MEDICAL COLLEGE, DECEMBER, 1880.

BY N. S. DAVIS, M. D.

Professor of Practice of Medicine.

GENTLEMEN, — We will talk to-day about the pathology and treatment of what is called pernicious, or malignant, chills; that form of periodical fever which assumes a dangerous character. Perhaps there is no one disease named in the catalogue that illustrates the necessity of studying the pathological conditions as a guide to our therapeutics, instead of mere names of diseases, better than this. For if we look at the various authors we find them describing quite a variety of cases under this head, differing widely from each other; and if we turn our attention to the ordinary practitioners in the profession who allude to them, it is quite common for them to say such a patient had a malignant or a congestive chill, and speak of him as having congestive chills five or six times. These are usually of that class who always magnify whatever ailment comes under their care, apparently for the purpose of getting more credit for the cure.

Malignant or truly pernicious malarial chills occur not very frequently in our country, but in the most intensely malarial districts cases are seen almost every year. Dr. Drake tells us they are found most frequent between the parallels of thirty-one and thirty-three degrees, which includes that belt in the southern states comprising the rice fields, the cane brakes, and the borders of streams and bayous opening into the Gulf of Mexico. According to Dr. Drake the next most common place to find them is along the Red River region of Louisiana, and the southern border of Lake Michigan, from Chicago around to St. Joseph. In the early settlement of the country they were quite common in the latter region, but with increase of population and its consequences they have become rare.

In Europe they have long been familiar with this variety of malarious fever, in some portions of Holland, Turkey, and Austria, and also on the western coast of Africa. These are the regions where this variety of malarious fever most frequently occurs, and consequently where its peculiarities are most familiar to the profession.

You will remember that in speaking of the *modus operandi* of malaria on the human system, I deviated from the opinions most commonly expressed on this subject, which are, that malaria, whether organic or inorganic, produces its primary impression upon the nervous structures through the medium of the blood. Instead of this, I claimed that its presence in the blood produced a primary and direct effect on the elementary properties common to all the tissues; namely, susceptibility and vital affinity; and that the nervous disturbance was only a part of this more general action. I further explained that it primarily caused an increase of the general susceptibility or excitability, coincident with a decided diminution of the vital affinity by which the tonicity of the tissues and the atomic movements are controlled. In speaking yesterday of the sympto-

matology of periodical fevers, I explained that the difference between the ordinary and the pernicious paroxysm was the more profound depression of the vital affinity in the latter. Owing either to the intensity of the exciting cause (malaria) or some peculiarity of the individual, the depression of that property is so great as to endanger an actual arrest of capillary circulation and molecular changes as they occur in the processes of secretion, nutrition, and disintegration; and hence the extreme danger of actual suspension of life in the paroxysm. Or, if reaction does not take place, it is liable to be incomplete, leaving the circulation, molecular changes, and temperature of some of the parts still depressed, even through the intermission. The essential pathology of the pernicious chill therefore is, that the play of vital affinity is so far overcome as to make the restoration of the natural atomic or molecular relations between the constituents of the blood in the capillaries and the organized tissues, extremely difficult. This being the essential feature of the disease, it is necessarily dangerous, because whenever the properties of the tissues become so involved that they lose their inherent power to attract new atoms from the blood and return old ones, as in the natural processes of secretion, nutrition, etc., there is not only imminent danger of the cessation of life, but there is also great difficulty in obtaining any effect from the administration of remedies.

In some cases in which reaction takes place it is not complete or uniform in all parts of the body and extremities. The parts most frequently left pale and cold after the general reaction, are the finger, toes, tip of the nose, and lobe of the ear. Such failure in any part, however limited, should be regarded as indicating the return of another and still more dangerous paroxysm.

Owing to the different degrees of intensity in the action of the malarious poison, or to the difference in the susceptibility of the several groups of organs, or to both, the cases classed as pernicious present considerable diversity in their symptoms and progress. For clinical purposes they may all be arranged in five groups, namely, the comatose, the spasmodic, the pulmonary, the choleraic, and the algid. This number might be reduced by uniting the first two groups in one, calling it the cerebro-spinal. In the first group here mentioned, the force of the morbid impression falls upon the brain, or more particularly upon the cerebral hemispheres, and so far suspends their function as to render the patient unconscious or comatose from the very beginning of the paroxysm. As these cases progress the coma may become hourly more profound, the face pale, the temperature low, pulse feeble, respiration irregular, and pupils dilated, until death supervenes. Dr. Hertz, in Ziemssen's Cyclopadia, speaks of cases that are not only perfectly unconscious, but have reached a stage of apparent suspension of the functions of life so as to appear dead. He speaks of a man who was actually supposed to be dead, and taken to the morgue for examination; but some signs of life being discovered he was returned to his bed, where subsequent reaction took place and he recovered. Such cases of apparent death are rare. In some of the cases in which a comatose condition presents itself a partial reaction soon takes place in which the face becomes deeply suffused, the head and trunk hot, pulse more full, and respiration hurried. In some of these cases the coma gives place to wild delirium, which may end

¹ Specially reported for the Boston Medical and Surgical Journal.

either in the supervention of sleep and an intermission, or the return of coma, general paralysis, and death.

For practical or therapeutical purposes it is important to distinguish these cases in which, at least, partial reaction occurs, from those just previously described. The one is accompanied by febrile reaction, with fullness of the cerebral vessels, while the other remains cold, the pulse weak, vacillating, and irregular, yet both are comatose. In the second group of cases, which I called *spasmodic*, the force of the disease appears to fall upon the spinal cord and medulla oblongata. In these, the paroxysm is ushered in, not with coma, but with severe muscular contractions, either continuous as in tetanus, or paroxysmal, as in convulsions.

In a previous lecture, when giving the general symptomatology of periodical fevers, I described to you some cases in which a prominent feature of the paroxysm was such a rigidity of the muscles of the neck as to keep the head drawn strongly backward or to one side, and others characterized by clonic spasms or convulsions. The latter are seldom seen in the adult, but are much more frequent in children under ten years of age. In all these spasmodic cases there is much danger that the muscles of respiration will become so involved as to fatally interfere with the functions of respiration and circulation.

In the third group of cases the force of the disease, instead of falling upon the brain or spinal cord, is manifested chiefly in the respiratory organs, and the patient, on going into the paroxysm or chill with its general phenomena of depression, feels great oppression across the chest; the breathing becomes laborious, the finger-nails blue, the lips leaden, and the pulse frequent and feeble, with impairment of circulation in the cutaneous surface. While the mind remains clear, though often inclined to drowsiness, the stagnation in the pulmonary capillaries and consequent dyspnea increases rapidly. At first there is a universal mixture of moist and dry râles passing rapidly into the submucous and mucous rhonchi, all over the chest from the clavicles to the diaphragm, posteriorly and anteriorly.

The accumulation in the lungs is sometimes so rapid that the air cells become literally overwhelmed by compression and oedematous infiltration in three or four hours, shutting the air off so completely that the patient dies directly from suffocation. One case of this kind came under my observation many years ago that terminated fatally in about eight hours. More recently, in consultation with another physician, I saw a case almost equally rapid in its progress, but which was arrested, and recovery took place.

In the fourth or choleraic group of cases, the force of the disease seems to fall more directly upon the digestive organs, causing in addition to the general depression and coldness, great epigastric distress and restlessness, with frequent turns of vomiting and purging, intense thirst, dryness of the mouth and fauces, coldness and blueness of the surface and extremities, and weakness of voice, constituting a group of symptoms so closely resembling a severe attack of epidemic cholera that the case would be readily classed as such if the latter disease should happen to be prevailing in the community at the same time. Generally, however, there are less muscular cramps, and the discharges less like rice water in appearance than in cholera. In some of this group of cases, especially in warm climates, and when the pernicious character manifests itself

after one or more paroxysms of a milder grade, more or less hæmorrhage accompanies the stage of exhaustion.

I recollect an instance occurring outside of the city limits, twenty years ago, in the latter part of the summer, where a man, past the middle period of life, had a periodical fever for four or five days, accompanied by looseness of the bowels, and which ended in a paroxysm of extreme depression, during which he had three or four copious discharges of dark grumous blood, and in less than five hours he was in a state of complete collapse, and soon died, apparently from the direct effects of the hæmorrhage.

Hæmorrhage in these cases may take place from the gums, from the mouth, and from the nasal passages, the renal organs, or into the subcutaneous tissues, just as we see sometimes in malignant cases of the eruptive fevers. I saw, not two weeks since, a case of measles where the disease manifested itself in this malignant form. A general hæmorrhagic tendency was developed so early that on the second day of the eruption there was more or less extravasation into the tissues, and an oozing of blood into the mouth, and the patient died within twenty-four hours from the time I saw her, which was on the evening of the third day of eruption. It was a young woman in the vigorous period of adult life.

A similar pathological condition is occasionally seen in the more malignant cases of all the varieties of idiopathic fever.

I have now described briefly the comatose and the spasmodic cases, which involve prominently the cerebro-spinal nervous centres, the pulmonary, or such as endanger life from suspension of the respiratory function, and the choleraic, involving most prominently the digestive organs. The last cases described, accompanied by hæmorrhage, are by most writers placed in a separate group called the hæmorrhagic. There is another variety still, that is known as preëminently the cold or algid group. Primarily all are more or less cold, but there is a class of cases where the patient becomes almost at once cold and blue, and ultimately his organic functions cease without any specific determination to one important organ more than another, unless it be to the cutaneous surface in the form of copious cold sweating. And even the post-mortem examination in these cases reveals nothing more than a paler and drier state of the tissues than natural. When death has taken place in the comatose groups of cases, the post-mortem examination reveals more fullness of the vessels of the brain, with more or less oedematous infiltration into the cerebral substance. In the spasmodic or convulsive group similar appearances are found in the spinal cord or medulla oblongata or both. In the pulmonary group the predominant post-mortem appearances are passive engorgement of the vessels and oedema of the tissue of the lungs. True hepatization or other inflammatory changes are very seldom seen. In the choleraic groups of cases the chief post-mortem changes are increased fullness of the vessels with softening of portions of the mucous membrane of the alimentary canal, with a similar condition of the spleen, and, less notably, of the liver.

All these post-mortem changes point directly to certain pathological conditions, such as general impairment of tonicity in the tissues, including especially the coats of the blood-vessels, and ready passive exudations wherever local determinations take place. These

are shown by the copious sweating from the skin, the still more copious serous and hemorrhagic discharges from the internal surfaces, the vascular fullness with œdema of the brain and lungs, and the actual reduction of temperature. In regard to the latter, Dr. Hertz mentions a case in which the clinical thermometer gave only 88° F. in the mouth, 86° F. in the anus, and 84° F. in the axilla. Such reduction of temperature, as well as the whole assemblage of changes I have described, clearly indicate a great impairment of tonicity, including muscular contractility, and of molecular changes, and innervation.

If these views, sustained alike by clinical observation and post-mortem examinations, are correct they furnish two leading and important indications for treatment. First, to bring about general and uniform reaction by the prompt use of such means as will most efficiently increase the tonicity of the tissues, the molecular changes, and the vaso-motor sensibility. If we succeed in this, and thereby conduct the patient safely to the commencement of a period of remission or intermission, the second indication is to bring him, as speedily as possible, so fully under the influence of some anti-periodic as to prevent the supervention of another paroxysm.

In endeavoring to fulfill the first indication, it has been, from the earliest period in the history of the disease, a common practice to endeavor to establish reaction and warmth by administering large doses of hot stimulating remedies internally and applying all kinds of heating and irritant applications externally. Hot whisky or brandy punch, with or without the addition of pepper, has been given most liberally, with external frictions, sinapisms, hot bricks, hot corn, bottles of hot water, and hot baths, and yet without the slightest beneficial effect on the patient.

Dr. Daniel Drake, in his valuable work on the Topography and Diseases of the Interior Valley of the Continent, states that he has seen the skin made *red* by hot frictions without the slightest effect on the temperature. In one case he saw the patient immersed in a hot bath containing a liberal quantity of salt, mustard, and whiskey; and in another the patient was enveloped in cloths or sheets wet with an infusion of Peruvian bark as hot as could be borne, and covered with oiled silk to prevent evaporation, but in neither was there any improvement in the circulation or the temperature. And he states as the result of his extensive personal investigations that both external heat and the internal use of what are called alcoholic stimulants are absolutely useless in the depression of a true pernicious paroxysm of malarious fever. From what we now know of the effects of alcohol as an anæsthetic to nerve sensibility, and direct retarder of molecular changes and capillary circulation, we should not only expect no benefit but positive harm from its use in these cases. Under the theory of internal congestion, especially of the portal system of vessels, bleeding, large doses of calomel, and various kinds of emetics have been tried, but with no encouraging results, except in a few cases when an emetic of salt and mustard appeared to aid in establishing reaction.

Dr. Milne Edwards many years ago demonstrated very clearly, by an ample series of experiments upon the living animal, that heat diminishes the general tonicity and relaxes the contractile tissues of the body, and that cold increases both by bringing the atoms closer together and strengthening the play of vital affinity.

The results obtained by Dr. Edwards have been fully confirmed by later observations; and whether you agree with me that malaria acts directly upon the elementary properties common to all living tissues, or indirectly through a primary paralyzing influence on the vaso-motor nervous system, as suggested by most writers, they point directly to the sudden and temporary application of cold as the most rational and efficient means we possess for arousing nerve sensibility, capillary circulation, molecular movements, and, as a result, an increase of temperature. I have repeatedly seen this power efficiently displayed in the treatment of cases of opium poisoning. In the case of a little child to whom the mother had given an overdose of laudanum by mistake, I was called in the middle of the night, and as I entered the room the child appeared to be breathing out its last gasp. I immediately caught a cup of cold water and suddenly dashed a part of it on the child's face and chest, which aroused two or three quick and full inspirations, followed by shorter and shorter ones, until another apparent stop; another dash of cold water renewed them, and for more than three hours I sat by the child repeating the dash as often as the respiratory movements failed, during which the poison was so far eliminated and the nervous sensibility restored that it was safe to leave the patient.

In using the dash of cold water for the purpose of establishing general reaction from the cold stage of pernicious fever, the patient should be stripped, and several gallons of cold water suddenly dashed over the head and trunk of the body, then quickly rolled up in warm dry flannel blankets for thirty minutes. If there is not a decided improvement in the pulse and temperature at the end of that time, unwrap him and repeat the dash, following it by the warm blankets as before. This process may be repeated three or four times, if necessary, but in most of the instances in which it has been tried one or two repetitions have been sufficient. I do not recommend to you this method of treating the pernicious chill on mere theoretical grounds, for it has had the sanction of direct clinical experience. So early as 1830, Dr. Fearn, of Huntsville, Alabama, one of the most eminent and successful practitioners in the Southern States at that time, adopted the practice with such success as to attract much attention and to win many followers in the South. He was residing in the belt of country most favorable for the development of this variety of malarious fever, and at a period of time when it was much more prevalent than it has been in later years. Only two cases have come directly under my observation in which the practice was adopted, and in both the result was favorable. One of these occurred more than twenty years since. The patient was a young woman in a family of hydropathic faith, and when they were told by the attending physician, and myself in consultation, that the patient might not live until morning, they took the case into their own hands, wrapped her in cold wet sheets for a pack nearly half an hour, then changed to warm dry blankets, from which time she began to improve, and in less than eight hours she had safely entered the stage of intermission.

While I have no doubt but that the sudden and alternate application of the dash of cold water and dry warmth constitutes one of the most efficient methods of establishing reaction, there are other remedies of real value, especially in some of the groups of cases I have

described, and which may be used either alone or in conjunction with the process just indicated. For instance, in those cases of the comatose variety where a partial reaction has taken place and the face is deeply flushed and the head hot, apply an ice cap to the head and back of the neck. In other cases, where they are equally comatose but pale and cool, instead of the ice cap bring the patient's head over a tub, and with a pitcher filled with tepid water pour a douche of two or three quarts of water over the occiput, repeating it once in from half an hour to an hour, and it will constitute one of the most efficacious means of relief. The same means are applicable to the neck and spine, in the group of cases described as spasmodic or convulsive, and to the chest in those cases where the lungs are involved. In the choleraic cases, accompanied by great restlessness, frequent vomiting and purging, with cold sweat, much collateral advantage may be gained by the judicious use of morphia and atropia hypodermically. If the heart's action is very feeble the injection of morphia and atropia may be alternated with suitable doses of strychnia. In the purely algid cases, as I have described them, in addition to the efficient application alternately of cold water and dry warmth, the prompt administration, either by the stomach or hypodermically, of strychnia and atropia, without morphia, will constitute the best treatment you can adopt.

Atropia is one of the most reliable remedies we have for checking excessive perspiration and increasing the blood in the peripheral capillaries, while strychnia is equally efficient in increasing muscular contractility, and thus strengthening the heart.

If by the foregoing means, or any other, the reaction is established and the patient approaches the period of remission or intermission, how shall we fulfill the second indication and most certainly prevent another paroxysm? I answer, bring your patient as rapidly as possible under the full anti-periodic influence of quinine, which is more reliable than any other remedy we possess. Give twenty grains by the mouth or ten grains by hypodermic injection on the decline of the paroxysm, or as soon as reaction is fairly established, and repeat the same at such intervals that three doses will be taken before the time for the next paroxysm to begin. A less quantity might be sufficient in many cases, but it is so important to make sure of preventing another paroxysm that it is better to err in giving a larger quantity than is strictly necessary than in not giving enough.

Half the quantities just indicated will be sufficient for the next day, and still less the next, after which the case should be treated with tonics, rest, and nutritious food, as in the convalescence from other severe attacks of malarious fever. The patient should be particularly cautioned against resuming active labor, either physical or mental, until his strength is well restored.

—The Imperial Sanitary Bureau of Germany is reported to be organizing a comprehensive plan for reporting all cases of infectious and contagious diseases occurring throughout the empire. Special post-cards are to be distributed among the chief medical officers and authorities of districts, who will send in weekly reports for inscription in the central register; and thus the progress of an epidemic will at all times be observable.

THE DIAGNOSIS OF LOCOMOTOR ATAXIA IN THE EARLY STAGES.¹

BY JAMES J. PUTNAM, M. D.

THE next symptom to which I would ask your attention is the *absence of the so-called patella reflex*, to which notice was called for the first time in this connection less than four years ago by Professor Westphal, of Berlin.

The method of making the test is familiar enough. Every boy knows that if he crosses his right leg over his left, and raps it sharply just below the knee, the foot will fly out with a jerk. What he does not know is that this is a spinal reflex, and one of the quickest of its family, taking place in health in the course of one six hundredth to three hundredth of a second, as has been proved by careful measurement both in Europe and in the physiological laboratory of our college. It is considered not unlikely that through the stretching of each other's tendons, antagonistic sets of muscles thus help, each, to keep the other in a state of relative tension. But leaving aside the physiological discussion of the phenomenon, which has already a voluminous literature of its own, we may come to the clinical fact that in certain diseases of the spinal cord, those, speaking in a general way, in which the muscles of the lower extremities are habitually in a state of slight rigidity or spasm, as in certain forms of chronic myelitis, this reflex is exaggerated, while in others, in which, as a rule, the muscles are more or less relaxed, it is absent. To this latter group belongs locomotor ataxia.

This statement is not, to be sure, strictly correct. For, in the first place, the patella reflex is often present in the first stages of locomotor ataxia, and, in the second place, it is occasionally present even in advanced stages. This fact has been confirmed by numerous observers. Thus, among others, Berger found it preserved in two cases out of eighty-two (that is, in two and four tenths per cent.), a high degree of ataxia being present in both of them. Out of fifty cases observed by Erb it was present but once.

On the other hand, Berger found it absent in early stages of the disease in seventeen cases out of nineteen, and in three cases it was absent at a stage where no further sign of the affection except pains in the legs was to be seen. In two of these cases the diagnosis was subsequently verified by the appearance of other symptoms, optic atrophy and vesical disorders. Plenty of other testimony to the same effect could be quoted.

It is impossible, as yet, to say exactly where in the spinal cord the lesion must be situated that is to give rise to this symptom. It may, indeed, be assumed, with Westphal, that the lumbar enlargement must be affected, and that in the cases where the reflex is still present this part of the cord has escaped, or at any rate has not been involved in the usual degree and manner. Physiological experiments have, indeed, proved that section of the lumbar enlargement at a certain level will destroy the continuity of the reflex loop through which the excitation, coming from the patella tendon, must travel before it reaches the quadriceps extensor muscle. (Tschirjew.)

Of course, also, serious disease of the posterior nerve roots, through which all centripetal impressions must pass before entering the cord, would necessarily

¹ Concluded from page 171.

injure the afferent portion of this reflex loop. In this case, however, it might be expected that the sensibility of the skin supplied by these nerves would be impaired or lost. It is, however, by no means always the case that this conjunction of symptoms is observed. On the contrary, the patella reflex may be lost without either the cutaneous sensibility being diminished or neuralgic pains being present (see, for example, Erb in Ziemssen's *Encyclopædia*), and Senator has recently ascertained that, in dogs and rabbits, the posterior columns, and even the posterior cornua of gray matter, may be thoroughly destroyed without this reflex being abolished.

Senator further discovered that the simple section of the outer half of the *lateral* columns at the level of the fifth to sixth lumbar vertebra would destroy the reflex in question, and that, too, without necessarily interfering materially with voluntary motion. He believes that the tendon reflexes are intimately associated with the tonic condition of the normal muscle, as was hinted above, though it may sometimes seem, owing to the grossness of our tests, as if the reflexes were lost while the tone of the muscle is preserved, because a slight loss of tone is not easily recognized. The relaxed state of the muscles of tabetic patients has repeatedly been commented on, and I have long been in the habit of pointing out to students that when such a patient crosses his legs the leg which is uppermost usually drops down so limp that the angle at the knee becomes almost a right angle. This is at times so striking that it would almost of itself suggest the diagnosis. The same thing is of course often enough to be seen with persons in health if they are tall and thin.

Positive anatomical evidence is as yet wanting that the lesion which in man causes the early disappearance of the patella reflex lies in that part of the cord indicated in these experiments of Senator's, but we may fairly expect something of the kind in the future, allowance being made, of course, for the difference in structure between the spinal cord of the rabbit and that of man.

It is a singular fact that this symptom, depending as it evidently does, on disease in a circumscribed portion of the lumbar enlargement, should often be present as one of the very earliest signs of locomotor ataxia, in conjunction with disease of very distant structures, such as atrophy of the optic nerves, alone.

This circumstance certainly seems to add strength to Leyden's view that the cerebro-spinal axis may be affected very early in its whole length, yet not severely enough to call out the usual array of classical symptoms. In other words, the longitudinal extension of the disease may be at or near its maximum long before the lateral extension or the intensity at any given point is complete.

The only case of presumed tabes in which I have personally found the patella reflex preserved is one that is of much interest, though in several respects peculiar and in need of further study. It is distinguished mainly by the presence of a strongly ataxic gait, which is closely like that of many tabetic patients, though it is not to be denied that it also suggests in a measure the "reel" of cerebellar disease. This has grown but very little worse since its first development, fifteen years ago. There has never been much pain till within the past year or so, and even this has not been perfectly characteristic of tabes.

The patient has complained much for some time

past of "numbness" of the skin over the back of one or both thighs, but loss of sensibility is not at all marked. Closure of the eyes materially increases his incoördination. The patella reflex is preserved on both sides. Other symptoms are wanting, including those which would especially suggest the presence of disseminated sclerosis or other forms of chronic myelitis.

The diagnostic value of this sign is not greatly lessened by the fact, of which there is no question, that the patella reflex is occasionally absent in health: for it would happen but very rarely that we should not have one or another additional symptom to guide us even in cases of beginning tabes. As a matter of fact, it is wanting in about one and one half per cent. of presumably healthy persons, as is shown by the statistics of Berger, who, with the assistance of Köbner and Kroner, examined 1409 individuals, among whom were 900 soldiers, with regard to this point.

Simple *diminution* of the reflex is not a sign to which much importance can be attached, and indeed, as Berger says, the contraction is often so little marked that it can only be recognized when care is taken to strip the leg bare, to see that the quadriceps muscle and tendon are stretched, yet not held rigid, and to strike a clean blow with a percussor hammer.

Other observers have found it absent in a larger proportion of healthy cases, but none of their observations have, I think, embraced so large a number of persons as Berger's.

I forbear to speak of the gastrocnemius reflex, partly because its absence is a sign of subordinate clinical value, and partly because there is some doubt (Gowers) whether its physiological significance is the same with that of the patella reflex. It is also much oftener absent in healthy persons.

I cannot close this subject without mentioning another observation of Berger's: that in one case, in which, under the use of nitrate of silver and baths, some improvement had taken place, the patella reflex, which had been lost, was found to have reappeared, when, after a lapse of five years, the patient presented himself again for examination.

The *early ocular symptoms* of tabes relating both to the motion of the globe, the iris, and the lens, and to the function of vision are full of interest.

To begin with the latter, it is well agreed that loss of vision, with optic-nerve atrophy, beginning, Charcot thinks, at the peripheral extremity of the nerve and working backwards, is a frequent precursor of the classical symptoms of tabes, and that it may precede the motor disorders by even five, ten, fifteen years and upwards, though it rarely exists long without one at least of the other signs, chief among which are the pains either in the head or the extremities and absence of the patella reflex. Charcot seems inclined to maintain that optic atrophy, when not due to neuritis, to diabetes, syphilis, or embolism of the retina, indicates either disseminated sclerosis, general paralysis of the insane, or locomotor ataxia. Of these conditions the two latter are closely allied, and the former generally presents symptoms by which it can be known. He states it as an opinion founded on long and careful study, for which as physician to the great hospital for incurables in Paris he has had exceptional opportunities, that a majority of the women admitted into the wards (of the Salpêtrière) with loss of vision show sooner or later more or less well-marked signs of locomotor ataxia. This is a strong

statement, but important enough even if only partially accurate. It seems at least to be certain that, taking cases of uncomplicated atrophy of the optic nerve as they run, the patella tendon reflex is oftener absent in them than it is in healthy persons, and it is also certain that optic atrophy is not infrequently met with where no cause whatever other than *tabes* can be found to explain it. Poisoning by tobacco, alcohol, and lead is of course always to be thought of, though all ophthalmologists do not agree (Allbutt) in attaching the same aetiological importance to tobacco poisoning that is accorded it by Hutchinson and other English surgeons. Moreover, there are special signs (central scotoma, etc.) by which atrophy from these causes can usually be distinguished. In the absence of such signs, we must look often and patiently for other indications of *tabes*. Dr. Wadsworth will recall the case of a young woman, twenty or twenty-five years of age, the servant of a friend, in perfect health, who became afflicted with progressive optic atrophy of the most typical kind, coming on absolutely without known cause. For some years she remained without further symptoms, and was then lost sight of.

Dr. F. P. Sprague was kind enough to refer to me, two years ago, a patient in middle life, in excellent health, a railroad conductor, where this same condition was present, associated with absence of the patella reflex, but with no other symptoms whatever of *tabes*.

I shall hope, at a future meeting, to present the subsequent history of these two cases to the society.

Scores of like instances could be quoted where the diagnosis was ultimately verified.

The point is worth insisting on, even to exaggeration, because for those not fully armed with suspicion it is difficult to keep their diagnosis so many years in suspense, or to believe in the existence of the unseen loop that connects groups of symptoms so removed from each other in character and in time of appearance.

Another case of great interest, which occurred in Dr. Wadsworth's practice, and which he kindly allows me to describe, must serve to illustrate not only this point, but also the fact that *tabes dorsalis* is related to mental disturbances, — both to those which constitute the typical dementia paralytica, and also, it would seem, to functional disorders, which may be of only temporary duration.

The patient is a man of middle age, and his history previous to 1871 offers nothing, I think, of special importance. At about that period his mind became temporarily impaired, and it would seem that his vision must also have begun to fail, since, not long after, his color sense had become so imperfect that he could not tell the green of the grass. Between 1871 and 1879 he was several times insane, and obliged to enter the McLean, and afterwards the Worcester, Asylum. Yet his condition was neither one of dementia, nor was it incurable, since for some time past he has been, so far as is known, quite well, and for nine months previous to his visit to the Massachusetts General Hospital in 1880 he had been employed regularly in doing some kind of manual labor at the University Press.

In 1873, while at the McLean Asylum, he was first seen by Dr. Wadsworth, and found to have atrophy of the optic nerves, with impaired vision.

On his coming to the hospital last year it was learned that for ten years past he had had characteristic pains in his legs (thighs, shins, knees, latterly heels). The pupils were found to be small, and not to

respond perceptibly to light, though they did act with efforts of accommodation. The patella reflex was absent on both sides. The gait was pretty good, except that he walked as if feeling for the floor with his feet, and he could stand with his feet together and his eyes closed, though it required an effort. It is now more than ten years since his symptoms first attracted attention.

Of course it is not necessary that absence of the patella reflex should be associated with optic atrophy to make the latter a significant symptom.

Among other observers, Dr. Wadsworth tells me that he has seen a case where characteristic pains had been present for four years, urinary symptoms, and impairment of vision, due to atrophy, for three months or more, and where there was marked incoördination; yet these reflexes were preserved, and there was but little or no alteration of sensibility.

This is the proper place to mention, without dwelling on the matter, that disorders of the special senses of hearing and of smell are occasionally met with as early signs. It is largely to Pierret, again, that we are indebted for what we know on this point.

In the auditory cases the symptoms closely resemble, or, more strictly, consist in, those of typical Ménière's disease, tinnitus with aural vertigo.

We may now hasten to consider briefly the symptoms relating to the muscles within and around the globe of the eye, which are well known to be often affected in the earliest stages of locomotor ataxia.

Every variety of strabismus may be met with; besides ptosis, and pre-hyopia from impaired accommodative power, as well. These paralyzes, or pareses, are all referable to slight changes, probably at the medullary centres of the third, fourth, and sixth and sympathetic nerves, and there is perhaps nothing that is especially characteristic about them, unless the fact that they are usually transitory.

It is not at all necessary for all the muscles supplied by any one nerve to be involved together, but this is not truer of the paralyzes due to locomotor ataxia than of those due to other causes affecting the central or even the peripheral distribution of these nerves.

The pupil is usually contracted, but in the early stages it may be of normal size, and even dilated, as Vincent shows, who examined all these points with great care on a large number of patients at the Salpêtrière.

The most characteristic feature of the pupillary symptoms is, however, the fact that the sphincter of the iris, while it loses the power of responding reflexly to light, continues to act in conjunction with efforts of accommodation. This is seen in the earliest as well as in later stages of the disease.

It happens but rarely that the strabismus of the early stages persists as a prominent symptom throughout, but this and several other interesting points are well illustrated by the following case which I saw at the Massachusetts General Hospital in consultation with Dr. Wadsworth, by whom it was first observed and diagnosed, and afterwards demonstrated before this society. I quote, by permission, from his notes.

The patient was a man of middle life and of healthy appearance, though his occupation, which was that of a longshoreman, had exposed him much to wet and cold. His history, which every pains was taken to investigate thoroughly, was as follows: For three years past he had had divergent strabismus of both eyes, but especially of the right. During the past six months before the time of the first examination the divergence of

the left eye had been getting worse. He had never noticed any unsteadiness of gait until within a few weeks, though the wharfinger afterwards said that he had observed it some time before. It must, however, have been but slight, for until within three weeks he had continued, in spite of the strabismus, to wheel his barrow over a single plank between wharf and vessel. For three weeks he had had "rheumatic" pains in the back, left side, and left thigh.

On examination there was found to be complete paralysis of both third nerves, including the branches to the iris and ciliary muscle, but not including the branches to the levatores palpebrarum. The fundus was normal; the patella reflex absent on both sides; and there were marked and characteristic alterations of sensibility over certain portions of the trunk, and the legs.

Once developed, the pains and the ataxia increased with great rapidity; urinary disorders set in; and within a few months after his first visit to the hospital the patient had become almost a prisoner in his room, because unable to get up and down the stairs without aid.

The objective disturbances of sensibility which are met with in the early, and still more the later, stages of tabes have long been made the subject of profound study, and in their gross features are too well recognized to need more than passing notice.

As with the neuralgic symptoms, so also with regard to these sensory disorders, it may almost be said that a disregard of rule and type, combined with occasional simulation of all types, is their most striking characteristic.

Still, there are certain groups of symptoms of this order which are more common than others, and indeed almost pathognomonic.

It is in tabes that we so often find the sensitiveness to pricking and pinching, and still more to deep pressure, much impaired, while the sense of contact and that of temperature are relatively well preserved. Sometimes such alterations of sensibility as these are found over one patch of skin, of greater or less extent, while the sensibility of a neighboring patch is relatively intact; or it may be, as Berger has pointed out, that as the case progresses the sensibility of one part, impaired at first, will improve, while that of other parts will become impaired in its turn.

Another observer has recently maintained that the reaction of the sensitive nerves of the skin to electrical stimulation may be widely different from that toward other equally powerful excitations.

Remak has repeatedly found that if the skin be exposed to a constant, minimal excitation by electricity the sensation called forth, instead of being persistent and uniform, comes and goes, swelling gradually to a maximum, then gradually disappearing again.

It is not only in the lower extremities that such disorders of sensibility are present; they are often found, even at an early stage, over various parts of the trunk as well, especially about the chest and between the shoulders.

A gross but convenient way to demonstrate the loss of the sense of pressure in the lower extremities, which is usually present to such a marked degree, is to make use of an ordinary spring balance, fastening to the hook at the lower end a sort of trapeze or stirrup made of a few inches of doweling, and a bit of string. When the foot, for example, resting on the ground, is

inclosed in this little trapeze, and a steady pull upwards is exerted on the upper end of the balance in the direction of the axis of the leg, while the knee is held firmly down from above, it is not uncommon to see the indicator of the balance mark twenty, thirty, even forty pounds, before the patient admits that he feels any increase in the pressure of the stirrup against the sole of the foot.

A well-known form of disturbance of sensibility consists in the delay shown in the conduction of impressions, and especially, strong impressions, which may amount to several seconds. Thus the patient, if pricked with a pin, may give one exclamation for the initial touch, and another a second or two later, and perhaps accompanied with a jerk of the leg, for the pain. Or a single prick may give rise to a series of sensations, slightly separated from each other in point of either space or time.

On the contrary, there may be hyperæsthesia instead of anæsthesia of the skin, especially over limited spots during the attacks of neuralgia.

Complete and wide-spread anæsthesia is somewhat rare, but I have seen one very interesting case where it was present over the entire lower extremities, part of the trunk, and (almost complete) over the upper extremities. A consideration of these cases or those where there is anæsthesia of one side of the face would, however, lead us too far astray from the symptoms characteristic of the early stages of the disease.

Neither shall I attempt to speak of the loss of the sense of the position of the limbs, important as it is to a complete picture of the affection, of the various mental symptoms with which tabes may be complicated, of the cardiac disorders, nor of the trophic changes in the seminal fluid (Buch), the teeth and jaws (Vallin, Bouehard), the joints and the bones. Of these latter affections, which though rare are sometimes met with in early stages, we have in the museum of the college some excellent models in plaster, cast, with Professor Charcot's permission, from the original specimens from which the plates in his book were photographed.

I will say, in conclusion, but a single word with regard to one relatively new point in the ætiology and one in the treatment of the disease.

It may be known that various writers, and of late especially Erb, have called attention to the great frequency with which a syphilitic history could be obtained from tabetic patients, and have drawn the conclusion that this disease probably plays an important part among the causes of tabes.

Very recently, however, Westphal, than whom no one is more reliable or accurate, has analyzed with great care both his own cases and those reported by others, and concludes that this supposed fact and the inferences from it are still without solid foundation, and that we cannot without further light on the subject reckon syphilis even among the predisposing causes of tabes.

The point in treatment is this: that within the past year, in as many as four cases of locomotor ataxia, the great nerve trunks of the upper or lower extremities have been forcibly stretched, originally with the view of relieving the severe pains with which in three of the cases the patients were afflicted. Not only was this result attained, however, but in all of these three the ataxic symptoms as well were conjured away. In the fourth case, in which no pains were present, this

result did not follow, and it has been stated that in one of the others there have been symptoms, after a long time, of a relapse.¹

The matter is still *sub judice*, but whether it proves of the immense therapeutic significance that it at first seemed to promise, or not, the results are of the highest scientific interest.

RECENT PROGRESS IN THE TREATMENT OF THORACIC DISEASES.²

BY F. L. KNIGHT, M. D.

BASIC CAVITY OF THE LUNG TREATED BY PARACENTESIS.

A PAPER on this subject was read at the meeting of the Royal Medical and Chirurgical Society in June last³ by Dr. R. Douglas Powell and Mr. R. W. Lyell. The case recorded was one of basic cavity following pneumonia and complicated with bronchiectasis. The operation afforded remarkable relief for some weeks, when death ensued from pleuro-pneumonia of the opposite lung. The operation was performed as follows: A medium-sized aspiration trocar was first thrust in at the eighth space, mid-scapular line, and a free incision having been made through the tissues down to the intercostal membrane, the fine trocar was withdrawn, and a full-sized hydrocele trocar inserted, which, after slightly enlarging the opening, was in its turn removed, and a large drainage tube introduced. Carbolic dressings were applied. A moderate quantity of secretion escaped from the wound (which gave rise to no serious bleeding), and discharge subsequently from the tube, although free, was never abundant. The expectoration and cough, however, at once almost entirely ceased. The wound was dressed daily under the carbolic spray, and injections of Condy's solution were used. The post-mortem examination revealed the presence of several intercommunicating cavities in the lower lobe of the right lung. The lobe was firmly adherent throughout, and a drainage tube passing through the eighth intercostal space entered a contracted cavity which was connected with the main cavity by a short dilated bronchus. Although at so high a level as the eighth space, it was only separated from the diaphragm by one eighth of an inch. It was evident that in contracting upon the tube the wall of the cavity had come in contact with and partially occluded its extremity. The rest of the lobe was densely consolidated by fibroid growth surrounding bronchiectatic cavities.

In their remarks upon the case the authors, whilst advocating the puncture of chronic basic cavities in suitable cases, deprecated interference with apex cavities, on the ground of its being rarely necessary or useful, and are averse, save in exceptional instances, to making incisions into acute basic abscesses of the lung, as the pleura would probably not be adherent. In future cases the authors would prefer to choose the centre of the cavity rather than its lowest point for puncture, where it is situated in the posterior lobe of the lung.

In the discussion, Dr. Symes Thompson said that owing to diagnostic difficulties the operation was not likely to become a common one, for cases in which a

pulmonary abscess sufficiently superficial could be diagnosed are few, but when there were grounds for believing in the existence of such a cavity, with adherent pleura and condensed lung, the question might be entertained.

Dr. Barlow, from his experience in empyema, urged the importance of a double opening, which dispenses with the necessity of injections.

Dr. C. T. Williams said it was important to discriminate the nature of the case. Cases of bronchiectatic cavities were not suitable, as they were mostly multiple. In ordinary phthisis the apex cavities, as a rule, drain themselves, so that no operation would be called for in them.

Mr. Erichsen said that from a surgical point of view the essential thing was to maintain drainage. Antiseptics were not needed, and were useless in such cases; they only excited irritation.

Dr. Powell thought it would be risky to attempt a double opening into these cavities. The immediate cessation of expectoration after the tapping was remarkable, showing that a small amount of fetid, acrid material would set up much bronchial irritation.

Mr. Lyell said it was impossible to have made a double opening.

CHEKEN IN WINTER-COUGH.

Murrell⁴ reports that he has used cheken in fifteen cases of chronic bronchitis. In all cases the patients obtained some benefit, and in most cases the relief was very marked. There was in a few days a decided improvement in the cough, expectoration was from the first easier, and soon diminished in quantity, and finally the dyspnoea was less. The fluid extract was the preparation used, two drachms in water every four hours, the dose being usually increased at the expiration of a week to half an ounce. Cheken, chekan, or chequen is an evergreen shrub closely resembling common myrtle, and grows abundantly in the central provinces of Chili. It is usually said to belong to the genus *Eugenia*, but by some it is referred to the closely-allied genus *Myrtus*. A good description of cheken, by Mr. Holmes, will be found in the *Pharmaceutical Journal* for February, 1879. It has also been highly praised by physicians in South America for its efficacy in phthisis, especially those attended by hamoptysis, and also in other diseases.

ATMOSPHERIC AND CLIMATIC INFLUENCE IN THE CAUSATION AND CURE OF PULMONARY DISEASES.

Dr. John C. Thorowgood⁵ differentiates phthisis of the lungs into two large groups: (1.) Those originating in catarrh or cold, or in some inflammatory attack in the chest produced by a cold. (2.) Those which are truly tubercular. This form comes on insidiously, often from no cold caught, from no privation of food, but simply from some inherent, often hereditary, vice in the system.

Patients of group number one often derive benefit from going to a mild climate, such as Ventnor or South Devon. When the chief agent for mischief that is to be combated is of an inflammatory nature, a mild, soothing air is the best. Where cough is severe and bronchial spasm frequent, a mild air is also suitable. In removing lingering inflammation after an acute attack on the chest, Dr. Thorowgood has seen excellent re-

¹ See Erlanmeyer, *Chl. fur. Nervenkunde*, etc., No. 21, 1880, Nov. 1. The reader is also referred, for an excellent recent sketch of locomotor ataxia, to a series of lectures by Dr. Bizzardi, in the *Lancet*, for 1880.

sults come from a sojourn at Torquay, Ventnor, and similar mild, warm health-resorts; but when the disorder has passed from the inflammatory stage to one that involves the general nutrition, and that is marked clinically by softening and breaking down of lung tissue, with night-sweats and copious purulent expectoration, he has never seen any good come of a residence in a mild, sedative climate. To cure a softening lung dryness of the air is essential. Whether a dry, cold, pure antiseptic air does really exercise its curative action by checking some septic process that is going on in the lung, or by annihilating certain morbid germs which engender tubercle, is not yet proved.

DAVOS PLATZ.

Dr. McCall Anderson visited this famous resort for consumptives during the summer of 1879, and has given us the results of his observations.¹ Davos is 5200 feet above the level of the sea, and is very prettily situated in a valley of considerable breadth, which runs N. N. W. and S. S. E., so that the sun shines upon it for many hours, even on the shortest winter day; its soil is dry, and the air is still, for, except towards the southeast, it is sheltered by high mountains in every direction, while, of course, it is highly rarefied, being nearly one fifth lighter than it is at the level of the sea. The ground is covered from November to March with snow, which is crisp and hard, and does not melt under the influence of the hottest sun, unless the Föhn, or generalized southwest wind, makes it appearance, a comparatively rare phenomenon fortunately, for it is very depressing, and apt to prove injurious to patients. The solar radiation is intense, although the air itself is cool and refreshing; this is illustrated by the fact that the temperature in the shade may be below the freezing point, while Casella's black bulb vacuum thermometer may register 130° F. in the sun, so that the snow does not melt upon the ground. In winter the solar radiation may be such that the thermometer may register even 165° F., but at night the temperature may fall very low, even some degrees below zero. Dr. Anderson gives the histories of a number of patients whom he had examined in whom pulmonary disease had been arrested by a residence at Davos. The cases, according to Dr. Anderson, which are most likely to do well there, are pretty much those which are most likely to improve elsewhere, namely, non-hereditary, uncomplicated cases of chronic phthisis, in which the extent of lung tissue involved is not excessive, with this proviso, however, that while the prognosis of phthisis with pronounced stomach-symptoms is not good at home, these are the very cases which should be sent to Davos, for there the appetite usually improves rapidly, and the digestive organs soon resume their normal vigor. It is a mistake to suppose, as some have done, that a tendency to hæmoptysis constitutes a contra-indication. Cases complicated with organic disease of the circulatory or nervous systems are unsuitable for treatment there, the place being too intensely stimulating for such persons. It is likewise contra-indicated where a very large amount of lung tissue is involved, or where the disease occurs as a complication of bronchitis, with emphysema; for in this highly rarefied atmosphere there is not a sufficiency of lung surface to aerate the blood, and such patients run the risk of being suffocated.

¹ Glasgow Medical Journal, xiii. 265.

ON THE INFLUENCE OF MOUNTAIN AIR IN THE TREATMENT OF PULMONARY CONSUMPTION.

Dr. J. Henry Bennett introduced a discussion on this subject at the annual meeting of the British Medical Association at Cork, in August, 1879.²

He said that he thought he was warranted in stating that it was now generally conceded, both at home and abroad, that the therapeutical views which reigned during the first half of this century with reference to the influence of climate on phthisis were erroneous. It was generally believed that a mild and moist, or a warm and moist, climate like that of Madeira or the West Indies, was the most calculated to arrest phthisis and to promote a recovery, when this was possible.

Dr. Bennett claimed for the late Prof. J. Hughes Bennett, and for himself, the merit of having contributed to establish the fact that tropical, or even semi-tropical, climates are inimical to the constitutional states which lie at the root of phthisis, and in most cases accelerate its progress, tending to prevent instead of to secure recoveries.

When we come to examine the therapeutics of phthisis, we find undoubted evidence that phthisical patients recover in every region of the northern and temperate climates, the regions where it has been more especially studied. We are told, however, that the highest inhabited regions of Europe — regions between five and six thousand feet high — constitute a specially desirable climate for consumptives, both in summer and winter, and offer greater chances of cure than any other locality. That cures can, and do, take place in these regions, even in winter, may be conceded to theory as well as practice if the habits of the sufferers are rendered hygienic. Many of those who have done well there, especially Germans, have consented to live in fine weather out of doors, whereas in the plains they had been, and would have been, shut up in unhealthy rooms. Much more, however, is demanded. It is asserted that there is an actual curative virtue in mountain altitudes, and that the chances of recovery are immeasurably increased by passing the summer or the winter, or both, at these elevations. This is the question to be discussed.

Within the last twenty years a considerable amount of information respecting the meteorological and health condition of high altitudes has been brought forward by French physicians who have resided and practiced on the high plains of Central America, at Mexico, on the plain of Anahuac at Santa Fe de Bogota, Quito, Potosi, and the sides of the Cordilleras Mountains generally. (Dr. Jourdanmet, Dr. Coindet, Dr. Domec.) They may be said to have established that phthisis is rare among the natives at these elevations, although common in the neighboring sea-coast towns, such as Vera Cruz and Guayaquil, and that in imported cases the progress of the disease is frequently arrested. Dr. Bennett said that he had lately been in correspondence with Dr. Domec, now a professor in the new university of Lille, who has recently passed four years at Quito, in Ecuador, a town of seventy thousand inhabitants and nearly ten thousand feet above the sea. He was one of the professors at the medical school, physician to the hospital, and engaged in active private practice. He saw only two or three cases of spontaneous phthisis among the natives during that time, and in all the cases of imported phthisis from the sea-coast that he met with the progress of the disease soon appeared to be arrested.

² British Medical Journal, July 10, 1880.

Different causes have been brought forward to account for this comparative immunity from phthisis on the healthy, bracing, but wild mountain plains of Central America, the most prominent one being the diminution of barometric pressure. The same immunity has been claimed for the mountain elevations of Europe, and the diminution of barometric pressure has been adduced as one of the chief reasons. The claim, however, proves to be an error as far as the Swiss mountains are concerned; so the explanation falls to the ground. Müller's work on the Statistics of Phthisical Mortality in Switzerland at once disposes of the argument that the diminution in barometrical pressure in the mountain elevations of Switzerland secures to their inhabitants immunity from phthisis. From Dr. Müller's tables it appears that phthisis destroys its victims at all elevations pretty nearly at the same ratio as in the plains. Thus the mortality, which in Switzerland is 10.2 per cent. at 1500 feet above the sea, is still 9.8 at an altitude from 3100 to 4100 feet for those who are engaged in industrial pursuits (laces and watches); but for those who are engaged in agricultural pursuits it is respectively 6 and 5 per cent. Above 5000 feet elevation, with an exclusively agricultural population, it is still 4 per cent., not very much below that of the agricultural population on the plains and at 4400 feet. In London, one of the centres of phthisis, the mortality is 12 per cent. In the mountain regions of Switzerland the mortality is nearly doubled for every one whose occupations are industrial or sedentary.

[While Dr. Müller's tables show that there is not an immunity from phthisis at any elevation in Switzerland, they show, also, that there are fewer deaths from phthisis in the elevated regions. For some unexplained reason the mortality appears quite high comparatively at the elevation selected by Dr. Bennett to sustain his position; but at the elevation from 2300 to 3000 feet Dr. Müller gives the mortality in the industrial class as 4.7, and in the agricultural class as 2.9 per cent. as compared with 10.2 and 6 per cent., from 200 to 1600 feet elevation. — *REV.*]

It cannot either be extreme cold that can give to mountain elevations an immunity from phthisis. The elevated plains in Central America are in the tropics; Quito is on the line; a snow level is many thousand feet higher, varying in the tropics from 11,000 to 17,000 feet, and the climate is mild, equable, and bracing, both in winter and summer. Dr. Domec states that at Quito, in a large room with doors and windows open day and night, he found the temperature to oscillate all the year round between 57° and 65° Fahrenheit. May not this free and constant ventilation in a temperate, equable climate be the cause of the freedom from phthisis, which at first sight appears so singular. In these towns of the mountain plains of tropical America there are poverty, destitution, famine, vice, and all other evils to which flesh is heir. Owing, however, to the ideal physiological climate the entire population lives in the open air. Dr. Domec states that other forms of tubercularization, such as tubercular meningitis, tubercles in the bones, or in the testicles, and acute miliary tubercularization of the lungs proved equally rare. He never met them in his medical or surgical wards, nor was pleurisy, acute or chronic, often seen; and yet various forms of scrofulous disease were so common as to impress a peculiar character on surgery. Catarrhal and inflammatory affections of

the aerial passages, of the bronchial tubes, and of the lungs were frequent and severe—a fact which he rationally attributes to the great power of the sun in a generally clear mountain atmosphere, and the sudden transition to shade temperature. This is a most important pathological fact, showing that severe inflammatory conditions of pulmonary organs do not lead to phthisis alone, *per se*.

Dr. Bennett thinks he has thus demonstrated his position. The undoubted immunity or comparative immunity from phthisis enjoyed by the inhabitants of the elevated mountain plains of tropical and subtropical America, from Mexico to the Argentine Republic, cannot be owing to mere elevation, to barometric conditions, inasmuch as phthisis reigns at all elevations, even above five thousand feet on the mountains of Switzerland; it cannot, either, be attributed to mere dry cold, as the mortality from phthisis is greater in Norway, Sweden, and Northern Russia than in London or Paris. What, then, can be the cause? In my opinion it is explained by the equable climate, ranging at Quito all the year, between 57° F. and 66° F. In such a climate the habits of the people secure constant and free ventilation night and day. The entire population lives, as it were, in the open air.

It appears that if we are guided by the laws of physiology, by those of general pathology, and by the meteorological facts brought from the mountain plains of Central or tropical America we are warranted in concluding that for Europeans the north shores of the Mediterranean offer the best attainable climates in winter. They constitute the nearest attainable approach to the American mountain plains, and admit of life being spent as there in the open air in the day, as also a free ventilation at night. Quito is a long, long way from us, or we might rationally make it a sanitarium for consumption. Mexico is easier of access, but not to be reached without great trouble and expense.

ARTIFICIAL INFLATION AS A REMEDIAL AGENT IN DISEASES OF THE LUNGS.

Dr. W. Y. Godbury, of Yazoo City, Miss., writes on this subject. It occurred to him, after reading a history of the use of condensed and rarefied air, that it was expensive and inconvenient, and the intervals were too long to accomplish the desired effect. He then sought for an instrument which could be used at the discretion of the patient, and one that would be in reach of the poorer classes. One was improvised by removing the spray tubes from a Richardson hand-ball and bulb atomizer, and inserting in place of the spray tubes a mouth tube. The mouth tube is inserted into the mouth with the left hand; a deep inspiration is taken; with the fingers of the same hand the lips and nostrils are closed, and the hand-ball worked rapidly with the right hand as long as the patient can bear it. In a healthy subject the operation is painless, and may be prolonged for a minute or more, but to a person with diseased lungs it is at first disagreeable, though not painful, and the patient complains that he cannot force in much air. However, practice soon enables him to pump the air freely into the lungs, and for a longer period each day. As soon as the distention becomes unpleasant or the need of an expiratory movement is felt, the instrument is withdrawn, to be replaced and reemployed in the same manner a few moments subsequently, the operation being repeated four or five times in succession. After frequent use it affords

great comfort to those who suffer from a feeling of suffocation, and have diminished capacity of these organs. A few cases are reported, in one of which a cure of consumption took place under its use. The writer, not having a large clinical field, wrote to Dr. J. Solis Cohen, of Philadelphia, to interest him in the method, and get his opinion of its value.

Dr. Cohen says it cannot be safely employed in all the cases in which insufflation of compressed air, as supplied from the apparatus of Waldenburg and others, are applicable, but it has sufficiently wide range of utility to commend it to professional attention, and in a certain class of cases it is of greater service than the bulky machines adverted to.

In patients liable to hæmoptysis or other hæmorrhages, and in certain cardiac and visceral disorders, the intrathoracic compression, if left to the patient, is apt to be too powerfully exercised, and thus to be absolutely detrimental. It is seldom safe to employ compressed air with a pressure exceeding from one sixtieth to one thirtieth of an atmosphere, and quite delicate handling of the ball-compressor is requisite to keep within this limit, while the size of the compressor prevents access of air in large volume, or at constant pressure. Thus, for general purposes, this plan, unmodified, cannot supersede the use of more complicated appliances.

Dr. Cohen calls attention, however, especially to the use of the Gadbury method as a mechanical expectorant. Time and again, he says, he has placed the little compressor in the hands of a patient with bronchioles and air cells clogged with mucus and pus, to see its use immediately followed by copious expectoration, to the great comfort of the patient. The process is repeated until it ceases to be followed by expectoration, and there is absolute or relative relief from the desire to cough, until reaccumulation indicates a renewal of the procedure at intervals of a couple of hours or longer, according to circumstances. Dr. Cohen has frequently availed himself of this method of clearing the air-passages previous to careful physical examinations, when abundance of moist râles were present, and has been better able to estimate the actual condition of the respiratory organs afterwards. Several of Dr. Cohen's phthisical patients relieved themselves by using this method morning and evening.

New Instruments.

A NEW URETHRAL SYRINGE AT LAST.

BY EDWARD WIGGLESWORTH, M. D.

The treatment of urethritis, from whatever cause, is by injections, and no less important than the fluid employed is the instrument used in the application of that fluid. Glass syringes break, are unequal in calibre in different parts of the cylinder, the wadding of the piston contracts in drying, and a portion of the fluid fails to be thrown out when the syringe is used a second time. The only material for syringes is hard rubber. Even more important is the *shape* of the syringe. The worst possible shape is the one which has usually been employed, namely, the syringe with a long straight nozzle, "No. 1," which reaches often past the seat of injury, the point of which scrapes and irritates the internal wall of the canal, and which is not well adapted to fully distend the meatus, nor to prevent the regurgitation of the liquid used. A few progressive physicians have used the *ear* syringes "No. 1, A" and

"No. 0," since these have shorter nozzles. The latter two, however, are of too small capacity to hold enough fluid to fully distend the urethra and obliterate the folds within which, "squat like a toad," lurks the virus. A syringe of greater capacity and even preferable nozzle is the desideratum, and that exists in the syringe of Sigmund, employed in Vienna exclusively, and largely elsewhere in Europe. This is figured in German works, but also in Bumstead and Taylor on Venereal Diseases, page 49, figure 3. A few of these have been made by Tiemann, but the price demanded [\$2.00] is too high, especially for that large class which is able to pay for the acquisition of, but not for the treatment of, its urethritides. For the last ten years I have endeavored to influence some rubber company to take the risk of putting Sigmund's syringe upon the market at a moderate price, but have only just succeeded. The Rubber Comb and Jewelry Company, 33 Mercer Street, New York, recently established under a most energetic management, has espoused the *pro bono publico* and a fair profit cause, and will hereafter furnish Sigmund's syringes to wholesale houses at a price which will enable them to retail for a dollar or even less. Its Boston wholesale agents are H. P. Emerson & Co., 33 Kingston Street. Codman and Shurtleff, Leach and Green, and others will have these syringes for sale. It is needless, I trust, to state that I have no interest in the syringe beyond the belief that it is the best as well as the cheapest. I ask all physicians, therefore, to recommend its use to their patients, its sale to their druggists. The syringe is known by the title of the "Royal" excelsior "P" syringe, which almost carries "hyperbole to a satire," but "Royal" is the trade-mark of all the syringes of the company; excelsior (if not supreme) the syringe is, and "P" is to be regarded not as a paronomasia, but as a contraction, which veils while it reveals. The accompanying "electrotype" will convey more clearly than words an idea of the exact size and shape of this new syringe, which I strongly urge upon the profession as the best syringe in existence for the treatment of a urethritis.

SOFT RUBBER VELVET-EYED TUBES FOR MAKING THE INJECTION IN GONORRHEA PAINLESS.

BY W. THORNTON PARKER, M. D.

I BEG leave to submit for the consideration of the profession the following points in the treatment of gonorrhœa:—

It is especially important to have a good syringe capable of thoroughly washing out the urethra with as little pain and irritation as possible. The syringes found in the drug stores are usually made of glass or rubber, with very small, pointed nozzles; they are apt to irritate the urethra, and are also objectionable for the following reasons: (1.) It is quite impossible to introduce the nozzle painlessly. (2.) It is difficult to compress the penis tightly about the nozzle without pain. (3.) The injection pours out at either side of the nozzle after introduction without entering the urethra far enough to be of any value. (4.) The constant use of the hard rubber, or glass, nozzle is apt to create an ulcerated spot where the point touches the lining of the urethra.

It is evidently important to avoid all these accidents to treat a case successfully. The cure of many cases is delayed, and the chances for stricture increased, because a good syringe can not be found. At least, I am sure that such has been the experience in my own practice.

It is difficult, even in the city, to find a bulb-pointed syringe, either of hard rubber or glass, of the right calibre for each case; and in small towns the ordinary glass syringe is all that can be had.

In Van Buren and Keyes' General Urinary Diseases, page 60, the practitioner is especially warned against "scratching and irritating the already inflamed mucous membrane," and also that "glass syringes should never be used."

To remove some of the difficulties encountered at present in the treatment of urethral inflammation, and to facilitate the injection of the urethra without pain, Messrs. George Tiemann and Company, of New York, have made for me some "soft rubber, velvet-eyed tubes with bulbs for making the injection painless."

The accompanying wood-cut gives a very good idea of the tubes.

They are about two and a half inches long, of three sizes, the bulbs corresponding with Nos. 13, 15, and 17, Tiemann and Company's American scale. They are made of pure rubber, soft and pliable. The movement to the right or left of the syringe in pressing out the fluid cannot cause pain because only the rubber tube beyond the attachment to the syringe is to be introduced; they are easily introduced painlessly, and compressing the penis about them to retain the injection is also painless. The bulbs have very thin walls. I find these tubes excellent in practice, and very highly appreciated by those who have been tormented with ordinary syringes. They fit easily on the nozzle of almost any syringe. The hard rubber ear syringe with the ring for self-injecting I find preferable to all others. In the "increasing stage" I recommend hot bathing of the parts night and morning (vide Van Buren and Keyes, page 60, *et seq.*), and the use, as an aperient, of Brewer's tartrate of soda, an elegant preparation, milder and better in every way than sulphate of magnesia or Scidlitz powders.

In the "stationary stage" I use the following injection, which, in the majority of cases, will give better results than any other injection, — at least such has been my experience in a large number of cases: —

Ry	Zinci sulph. carbol.	3i.	3 ip.
	Aque distil.		3 vi.
	Mucil. acacia		3 i.
	Fl. ext. opium aq.		3 i.

M. Ft. inject. S. Use night and morning.

These tubes are packed nicely in a little box, and can be obtained by mail from Messrs. Tiemann and Company, with or without the syringe.

PLYMOUTH, MASS., February 11, 1881.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

JANUARY 29, 1881, fifty-eight members present, DR. HODGES in the chair.

DR. HENRY O. MARCY read a paper on The Development of the Osseous Callus in Fractures of the Bones of Man and Animals. The paper was illustrated by numerous photographs of various specimens, showing the repair of fractures and a series of microscopic sections of the bones of the rabbit. The animals, twenty in number, had been killed at different dates, from the third day until the fourth week, and microscopic sections of the injected specimens had been very skillfully prepared by Dr. A. F. Holt, of Cambridge, under whose direction they were projected upon the screen by the aid of the oxy-hydrogen light.

At the beginning Dr. Marcy stated that his studies in this direction had been prompted by his clinical observations upon the repair of fractures under various modes of treatment, and especially from his belief that after careful adaptation and complete rest there occurred under favorable circumstances a primary union of bone, not unlike that taking place in the repair of other tissues.

After a review of the teachings upon the subject, from the time of Galen until the present, each factor which could enter into the processes of repair was analyzed in detail. From its intimate connection and bearing upon the subject, the histological processes of the normal development of bone was also presented and illustrated. The first factor of importance in the formation of the soft or provisional callus examined was the blood. The conclusion arrived at was, that it could be of little value under the most favorable circumstances, but might even be a serious obstacle to rapid repair.

The part taken by the medulla, although more important, must, to be of much value, be exercised within special limits. The medullary parts of a fractured bone must be in a somewhat close relationship, in order to be of avail in the production of the so-called internal callus.

Careful studies in detail, with many beautiful microscopic illustrations, were made, showing the part the periosteum takes in the repair of bone, and the conclusion at which Dr. Marcy arrives is quite at variance with the opinions usually accepted, as taught by Paget and Billroth.

Certain views of Beale and Ercolani he accepts as demonstrated, and believes that at the place of fracture the fibrous sheets of the bone, the superficial layer at least of the periosteum, takes no part in the repair, but undergoes a process of absorption or even necrosis; and

shows, as emphasized by Ercolani, that it is to a new periosteum covering the soft callus that importance should be attached.

This new and very vascular periosteum must be placed in close relationship with the exuded cellular elements upon which it impresses its osteo-genetic action.

A considerable number of specimens of fissures or partial fractures were shown where union had failed, or taken place only in part, and absorption instead of osseous deposit had occurred along the line of injury.

This condition after certain fractures, especially of the skull, is alluded to by no one, so far as the reader knew, except Professor Ercolani, and the lesson which it teaches on the repair of fractures is evidently of the first importance. From it several facts of great value may be deduced. First, that the periosteum at the place of injury is so impaired that it loses its osteo-genetic function, and secondly, that the canals of Havers do not enter largely into the repair processes in fractures, as taught by Billroth. The many specimens shown demonstrated that in the vicinity of the fractures the Haversian system had undergone no important change either in its blood supply or cellular exudation into the canals.

Dr. Marcy concludes, from his studies, that the most important conditions in the process of repair are first, that as early as the sixth or eighth day the exudation from the parts surrounding the fracture, so-called provisional callus, is covered in with a smooth shining membrane, the new periosteum. Second, that at the place of injury the old periosteum is destroyed, and third, that the exuded elements have an individuality peculiarly their own, and develop into osseous substance in conformity with fixed laws. The factors which enter into the repair of a fracture differ and unite in various ways to produce the final result of consolidation. Strictly speaking, there is no primary union in bone, but the conclusion is reached, which happily has been arrived at from the experimental standpoint of practice, that by careful and complete adaptation of the fractured parts, we place the various factors of repair in such relation that they must readily combine to aid in the restoration of the part, and by retaining them undisturbed for a certain period we assist in producing the most satisfactory results.

Dr. A. T. CABOT expressed his interest in the display of specimens shown by Dr. Marcy in illustration of the subject. He said that the time being short he should confine himself to the discussion of a few points in which he differed from the views advanced by the reader. First, in regard to the disappearance of the periosteum at the point of fracture, upon which much stress had been laid; Dr. Marcy considered the word periosteum to apply only to the fibrous mantle enveloping the bone, whereas the periosteum is now described as consisting of two layers, an outer layer and an inner cellular layer, and it is this inner one which provides for the growth of the bone, and supplies the bony periosteal callus in fractures. This point had been well shown in several of Dr. Marcy's sections, in which the bone had been merely cracked, without rupture of the periosteum. In these cases the proliferation of the cellular layer of the periosteum, lifting the intact fibrous layer above it, was quite evident. In these cases, where the fibrous layer was ruptured and the edges separated, a union of the divided edges took place much in the manner that the skin bridges

over a superficial wound, and beneath this restored layer the cell proliferation and final ossification went on as in the previous case. In studying the formation of a callus it should be remembered that, besides the processes of repair, we have inflammatory changes, which mask and frequently interfere with the reparative processes. It is to be regretted that the specimens shown by Dr. Marcy, to illustrate the absorption of bone about fissures, were all old and dry bones, with, in many instances, no history of the nature of the injury producing the defect. In one or two cases, where a history was obtained, the injury had been severe, by gun-shot or sabre blow, and in these the periosteum and superficial portions of the bone may well have been destroyed by the violence of the injury and the subsequent inflammation. It seems unfair, therefore, to draw from such inadequate material any conclusions as to the action of the Haversian systems or the periosteum in the formation of callus.

Dr. FITZ said that the microscopic sections seemed to clearly illustrate the process of callus formation as usually described, especially with regard to the periosteal and medullary changes. He understood the reader to insist upon the absence of injection of the Haversian canals in the specimens shown as disproving the views of Billroth, who describes a dilatation of these canals as one of the first changes in the neighborhood of a recent fracture. It seems possible, however, that Dr. Marcy's injections did not reach the ends of the fractured bones. In macerated specimens a notable porosity is observed, showing that such dilatation does occur. He agreed with Dr. Cabot in thinking the specimens shown by Dr. Marcy rather illustrative of absorption about fissures, than admissible as evidence that bone formation in the repair of fractures did not take place from the broken ends. The gaps were apparently due to inflammation and consequent destruction of the parts, rather than in any way connected with a reparative process.

The society tendered a vote of thanks to Dr. Holt, of Cambridge, for his excellent illustrations of the sections.

Recent Literature.

A Practical Treatise on Diseases of the Skin. By LOUIS A. DUHRING, M. D., etc. Second edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co. 1881.

"Read, mark, learn, and inwardly digest, for we have here the precious life-blood of a master spirit, infinite riches in a little room."

It is now nearly two years since the first edition of Dr. Duhring's treatise, *facile princeps* among works upon dermatology in the English language, was exhausted. The present edition is virtually a new book with a good deal of original matter upon certain rare diseases. Everything has been carefully revised and the views of the author more fully elaborated, as in the chapters upon scleroderma, morphea, and atrophy of the skin; and we must also add those upon pompholyx (cheiropompholyx) and dysidrosis; hæmatidrosis ("bleeding stigmata"); hypertrophy and atrophy of the hair; syphiloderma; scrofuloderma; and carcinoma. The volume has been enlarged to the extent of about one hundred pages and the size of the type re-

duced; unnecessary words and sentences have been stricken out and others condensed, thus affording space, without materially enlarging the size of the original volume, for new articles upon uridrosis, phosphorescent sweat, urticaria pigmentosa, dermatitis circumscripta herpetiformis, impetigo herpetiformis, pityriasis maculata et circinata, dermatitis exfoliativa, d. medicamentosa, d. gangrenosa, d. papillaris capillitii, fungoid neoplasma, tuberculosis cutis, podelcoma, anidum, perforating ulcer of the foot, and myoma cutis, articles demanded by the unprecedentedly rapid forward strides of dermatology, the discoveries in which have outnumbered those of any other specialty in medicine within the last few years. The vague name dermatitis has hitherto charitably covered a multitude of diseases, and concealed much ignorance, and needed investigation. We recommend the chapter under this head to the general practitioner as sound and practical, and almost exhaustive as to facts.

A good deal of physiology of the skin has been incorporated in the volume, following closely that good and careful observer Recluz; the chapter on anatomy has been largely rewritten, and two new illustrations have been added, one of the general anatomy of the integument, the other showing very beautifully and correctly the rete and horny layer according to most recent studies; both by Dr. A. Van Harlingen. American work has been brought forward also in the text; the observations, among others, of Dr. J. C. Warren having a prominent place in the article upon subcutaneous connective tissue. The views expressed as to alopecia areata are quite different from those of the first edition; the prognosis expressed is less favorable. Morphea has passed over from the atrophies into the hypertrophies. The pathology of lupus vulgaris has been carefully worked over, and Kaposi's views are endorsed. Under scrofuloderma we note two new forms; one, the "small pustular," being entirely so. The remarks upon "fungoid diseases of the skin" are new and of much interest; so, also, the chapter upon impetigo herpetiformis, which, though short, brings forward original facts tending to lessen the former unfavorable nature of the prognosis. Dr. Duhring has seen the disease upon men; Hebra met with it only in pregnant women, and therefore described but one phase of its symptoms and but one set of lesions. We rejoice that Dr. Duhring has at last substituted lepra (leprosy) for the ponderous "elephantiasis graecorum," and for the Barbadoes leg (elephantiasis arabum) employs the simple term elephantiasis. Pediculosis is a good term, but hardly applies to phtheirus (the crab louse), still it is preferable to phtheiriasis, which applies to no louse except the "crab." Fibroma molluscum we regard as anatomically preferable to molluscum fibrosum. Nor does the author state his reasons for inverting the nomenclature of Hebra as to sudamina and miliaria. Lichen ruber's reinstatement, in place of L. plaous, we hail with joy. We should prefer to have the cheloid (chele, crab's claw) of Alibert spelled thus, rather than confounded with the keloid of Addison (kelis, a horn) now classed as morphea. Pellagra we still regard as belonging rather to the exudative erythematous than to the neoplasma, and, generally considered, we note the absence of the contagious inflammatory processes, variola and vaccinia, scarlatina, morbilli, and rubella (rubeola), which might well have been touched upon even though not considered at length. Under acne we find no allusion to the very

practical point that preparations containing sulphur preceding or following those containing mercury or lead cause a black color when the second salve is applied. We trust that Dr. Duhring may, in his next edition, adopt the international metric system of weights and measures. As we are no "mousing owl," and can find nothing else to "hawk" at, we finish as we began, namely, Dr. Duhring's treatise is the best in the English language, and, for American objects, the best in the world. E. W.

Neurological Contributions. WILLIAM A. HAMMOND, M. D., assisted by WILLIAM J. MORTON, M. D. New York: G. P. Putnam's Sons. 1881. Vol. I. No. 3.

Referring to the announcement on the last page of this publication, it will be seen that four numbers, to comprise the first volume, were promised for 1879. As the number before us is No. 3 of Volume I., it is evident that it is a little behind time for 1879. But if behind as a volume, it is neurologically well up to the present time. We say neurologically, for we think when Dr. Hammond leaves the management of nerves to criticise the management of insane asylums, he sometimes makes mistakes, as a man always will who has not had practical experience within an asylum.

Our space being limited, we shall be obliged to condense our remarks, dwelling more particularly on the portion devoted to insanity.

The entire number is made up of contributions from Dr. Hammond, Dr. Morton not having favored the subscribers with any reports of clinics. Nearly all the contributions have been read before the New York Neurological Society. No. 1 is on Thalamic Epilepsy, and has been already reviewed in the columns of this JOURNAL. No. 2 relates two cases of Neuralgia of the Testis, prefaced with a few remarks.

Case I. was in a male, of fifteen months' duration, and probably induced by excessive sexual indulgence. The pain was of a sharp, lancinating character, not confined to the testicle, but extending up the cord as high as the external abdominal ring. The cremaster muscle was, during the continuance of the paroxysms, the subject of strong spasms, which added greatly to the agony of the patient. Various methods of treatment were tried without any benefit, until, finally, pressure applied to the spermatic cord, so as to compress the nerves, was applied by the use of a little wooden test-tube holder, slightly modified, with a rubber band about it. The instrument was made to compress the cord as high up as possible. Pressure of the finger was exerted in addition. In Case II. the treatment was slightly changed by the use of an apparatus similar to a lemon-squeezer, so arranged that the blades could be brought closer together or separated by means of a screw. Both of these cases were at once relieved, with no return of the symptoms at the date of writing, six weeks afterward.

Contribution III. is entitled Myxoedema with Special Reference to its Cerebral and Nervous Symptoms. The first account of this disease was given by Sir William Gull in 1873. Subsequently Dr. Ord, Dr. Dyce Duckworth, and Dr. George H. Savage each wrote on the subject; the latter describing its nervous symptoms. These appear to be very decided. The intellect is notably weakened; the memory is imperfect; and the patient experiences lack of confidence,

both as regards mental and physical power. The special senses are more or less perverted, and there are sometimes hallucinations or delusions; the most ordinary mental condition met with is, however, a lassitude or stupidity resembling the state known as acute dementia. The writer then describes a case, which gives a very good picture of the disease, and should be read entire. The writer agrees with Dr. Savage in the opinion that the mental symptoms are the result of brain disease, probably due to the deposit of the mucoid tissue around the cells of the nervous centres.

Contribution IV. is upon The Therapeutical Use of the Magnet, and is exceedingly interesting. Dr. Hammond uses magnets of the horse-shoe form. It is better to have them all of one size, as they can then be bound together and their power greatly increased. The magnet was tried in many cases with good results. It appears to the writer that all these cases, as well as those of hysterical hemi-anesthesia, which have been reported as being cured by the magnet and other applications, by Charcot and his pupils, are instances in which, if there were any organic lesion at all, this was mainly situated in the optic thalamus.

The last paper of the volume On Obscure Abscesses of the Liver, Their Association with Hypochondria and other forms of Mental Derangement and Their Treatment, is an extension of a paper published in the *St. Louis Clinical Record* for June, 1878.

On page 61, Suggestions for Improvements in the Management of the Insane and of Hospitals for the Insane in the State of New York, are given in compliance with the request of the New York Senate Committee appointed a year ago to investigate the insane asylums of New York. We do not propose to criticise Dr. Hammond's suggestions with reference to their bearing on the New York insane asylums; but to briefly consider their practical utility as applied to all insane hospitals. Suggestion 1. says that every letter of a patient should be forwarded if addressed to a state official or other person in authority, or, if addressed to other persons, to the Commissioner in Lunacy, who should decide whether it should be sent to its destination or not. The superintendent should have no power to detain letters. We can see no advantage to be obtained by the carrying out of this suggestion, as no one can ever be so competent to pass judgment on letters written by patients as the medical officers in charge. A very large portion of letters written by insane persons are a mass of scrawls, frequently so vulgar and indecent as to be fit only for the waste-basket. It would be throwing unnecessary work on a Commissioner of Lunacy, and take away one of the moral means of treatment of the medical officer. In many cases, one of the most reliable sources of information of a patient's mental condition is in his letters; and in such cases they should be preserved with his hospital history to give a clear picture of his disease. While it is well that the patient should be able to reach the Commissioner by letters unseen by the superintendent, to deprive the latter of all power would reflect on his honesty and undermine his influence.

Suggestion II., that only a medical officer of an asylum should be allowed to order a patient placed in mechanical restraint or seclusion, is a good one; and is generally practiced in well-regulated institutions, and it is also common in most of them to keep a record of the amount of restraint used. This book, as sug-

gested, should be opened for inspection by officials in authority; but we can see no possible reason why the counsel and family physician of the patient should have access to such a book, as they are the last persons fitted to pass judgment upon how much or how little restraint is needed by him, and the chances are that such knowledge would be an injury rather than a benefit to him.

Suggestion III. recommends that forms of mechanical restraint should be designated by law or regulation. To this suggestion we cannot agree, believing, as we do, that our legislators are not the ones to lay down rules concerning such an important part of the insane patient's treatment as the use of mechanical restraint.

Suggestion IV., that forcible feeding should be done either by a medical officer, or in his presence, is a good one. In our opinion, the stomach-tube should be used only by the medical officer; and in our experience this is the plan followed in well-managed asylums.

Suggestion V., that the counsel and family physician of any lunatic should always be allowed access to him, is undesirable. There are times when these persons may, without injury, see the patient; but, as at other times he may be excited and permanently injured by such visits, some modification of this suggestion would serve a better purpose.

Suggestion VI., that no person should, against his will, be confined in a lunatic asylum unless it is distinctly stated in the affidavit that such person cannot, with safety to his own life and property, or the lives and property of others, be allowed to go at large, we regard as entirely impracticable. The treatment of the insane person at an asylum must depend solely on his mental condition, and the fact that he is, or is not, dangerous cannot be the criterion to decide the question. If we wait for some outbreak of violence we may go over the time when an acute case is most curable, and in many cases we may never know of dangerous impulses until they are betrayed by some act of violence. In most cases of insanity, patients require a change of surroundings, a removal from all the scenes of daily life which have been instrumental in leading to the disease. The question will be, To what place, or what institution, shall he be removed? Unfortunately, the number of small, well-managed retreats is so limited, and the prices charged at them are so large, that in deciding the question they cannot, in most cases, be taken into consideration. When, therefore, the important question of removal from home is to be settled, and for the patient's welfare is imperatively necessary, we have only our large insane hospitals at our disposal; and it is our experience that they are, taking all things into consideration, vastly the best places for the treatment of all but a very small proportion of cases.

Suggestion VII. recommends a board of visiting physicians, whose duty it should be, at stated periods, to visit the wards of the institution; to consult with the superintendent as to the treatment of patients; and to examine into the system of management. The object of this suggestion is to assimilate the management of the insane hospital to that of other hospitals. We hope that this suggestion, which is now being tried, may have a trial in Massachusetts; for we welcome any increased means of treatment, even if of doubtful utility. We are, however, of the opinion

that this experiment will result in failure, as it will be almost impossible to find properly qualified physicians in our large cities who will be willing to make the long journeys necessary to reach most of our insane hospitals, which are frequently situated at remote points. In order to be of much service as consultants they should make very frequent visits; as only in that way can they get much knowledge of the condition of patients. A much better system than a board of physicians making visits of long intervals would be a board of attending physicians who should daily visit patients at the hospital, and take the whole responsibility of their treatment, giving instructions to the medical internes as to treatment during the intervening time between their visits. Unfortunately, however, this system cannot be generally practiced, for the same reason of the distance of the hospitals from large cities, as referred to above.

Suggestions VIII. and IX. refer particularly to the State of New York, and need not be considered here.

Suggestion X., recommending the examination and licensing of physicians desiring to keep private institutions for the treatment of insane persons, is an excellent one, and should be adopted in all States.

The neurological portion of the work is valuable, and of interest to all persons engaged in the study of nervous diseases; but the portion treating of insanity is quite foreign to the subject, and a decided injury to the entity of the volume. Take that out, publish the book as a monograph, with strong linen covers, and it would be well worth a place on the library shelves of the progressive physician.

On the Use of the Cold Pack, followed by Massage, in the Treatment of Anæmia. By MARY P. JACOBI, M. D., and VICTORIA A. WHITE, M. D. New York: G. P. Putnam's sons. 1880.

Eleven cases of anæmic patients are reported in detail, and we cannot read this report without commending in high terms the patience and faithfulness with which the authors have recorded their observations. This carefulness allows a very thorough criticism, and the sincerity, patience, and close attention is worthy of imitation by other medical writers. We, however, cannot attempt to give even an outline of the deductions which Drs. Jacobi and White have drawn from these cases, because a fair recapitulation would occupy too much space; yet the attention of readers is necessarily arrested by the fact that four of these anæmic patients had obstinate constipation or colitis, and four had decided uterine complications; the treatment was very properly directed to the relief of these complications and not until their removal did the patients show any improvement in general health. Iron was freely administered to seven of the patients from the very outset of the treatment; yet it is fair to remark that the ferruginous tonic had been used prior to the treatment of the pack and massage without any material advantage. From a careful survey of these cases it would seem, then, as if the anæmia was not relieved merely by the hydrotherapeutic and massage treatment, but by a combination of the relief of functional disturbances, by rest, by iron, and by the excitation of cutaneous and capillary circulation, as effected by cold pack and massage; in other words, to a relief of digestive and circulatory atony and of nervous debility, by which food as-

similation and general tissue nutrition might be promoted.

The details of urea elimination as given in tabular form are not of much use, because no comparison is made of its elimination by amount of food and drink before and after treatment.

The summary of scientific information upon the variations in capillary circulation of organs and tissues which is given in this book is prolix and extremely valuable to any one who will patiently master the technical terms and wearisome verbiage.

Compendium of Microscopical Technology. By CARL SEILER, M. D. Philadelphia: D. G. Brinton. 1881.

There is a great deal of practical value in this little book. The author is well fitted for such a task and the reader feels that the directions are the result of actual experience. We will notice but a few points. Dr. Seiler thinks the following formula the best for softening bone:—

Chromic acid	1 gram.
Nitric acid (C. P.)	2 c. c.
Water	200 c. c.

He hardens large pieces of animal tissue, as, for instance, a whole brain, by a mixture of equal parts of Müller's fluid and alcohol, which is changed daily, and in course of time, varying with the size of the specimen, replaced by alcohol. The directions for injecting are very minute, but we cannot conceive the advantage of injecting an animal as large as a cat with a two-ounce syringe. The point on which we differ most decidedly from the author is in his estimate of micro-photography. He says truly enough that drawings will be "tinged more or less by the imagination of the draughtsman, and will be more or less diagrammatic in consequence." We are not inclined, however, to look on this as a disadvantage. It gives an idea to the student which the vast majority of the photographs we have seen do not. The latter may be impartial witnesses, but they are at once so confused and so reticent that little is to be learned from them. It may be, however, that micro-photography has a future. The book concludes with a tabular view of the course and minute appearances and the clinical characteristics of tumors. Though the book does not contain much that is new we can heartily commend it on account of the justice, clearness, and minuteness of the directions. T. D.

Revelations of a Boston Physician. By CHARLES WISTAR STEVENS, M. D. Boston: A. Williams & Co. 1881.

This book is composed of thirty-three chapters, giving as many sketches, intended to illustrate the miseries of the very poor, the delusions of diseased imaginations, the sham diseases of sham patients, and amusing episodes occurring during the course of real sickness. These were mostly drawn from an experience of the last twelve years, as physician to the board of overseers of the poor, and are said by the author to be true, or substantially true.

To some of the sketches the imagination, we should judge, had been allowed to add slight embellishments. The collection is intended, apparently, rather for the general public than for professional readers.

Medical and Surgical Journal.

THURSDAY, MARCH 3, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY, No. 4 PARK STREET, BOSTON, MASS.

THE NEW YORK STATE BOARD OF CHARITIES.

IN addition to its annual report for 1880, the New York State Board of Charities has presented to the legislature at Albany a special report prepared by a committee of its members appointed for the purpose, upon the matter of a resolution adopted by the Assembly of 1880, to the effect that the State Board of Charities should be requested and instructed to examine into the whole question of the appropriations for charities in New York city (amounting to the sum of \$2,600,000 annually), and the propriety and proper amount and distribution of such appropriations, and to report to the legislature the result of their investigation and their recommendations upon the subject. In the outset of their report the committee state that the fact that there is no limit beyond which the sum spent from the public funds of New York city for the support of the delinquent and dependent part of the community may not be increased makes the matter one of very great moment, while the alarming and disproportionate rate at which this sum has increased, as compared with the increase of the population, during the last thirty years, renders it imperative that the facts of the past and the present and the dangers of the future should be thoroughly understood. A table is given which shows that while from 1850 to 1880 the population increased 134 per cent., the cost for charities and correction (paid for entirely by taxation and license fees, not a cent of the amount coming from voluntary contributions) increased 539 per cent. In the same period of time Boston shows: increase of population, 165 per cent.; increase of cost, 330 per cent.; while Philadelphia shows: increase of population, 133 per cent.; increase of cost, 112 per cent.

The report then goes on to mention that there are in the city of New York eight classes of what are called "charitable institutions" receiving money from the public funds, which are enumerated as follows:—

First, those under the charge of the Commissioners of Public Charities and Correction, which, on December 31, 1879, contained 8466 inmates, and the appropriation for the support of which for the year 1880 was \$860,000. The appropriation for additional buildings was, besides, \$154,200. The Board of Estimate and Apportionment of the city have full control and authority to appropriate for these institutions such sums as seem to them necessary, and, as a rule, a sum

less than that asked for by the commissioners, and less than is really necessary is appropriated.

Second. Institutions which receive, in accordance with special acts of the legislature, a *per capita* allowance for each inmate admitted, sufficient or more than sufficient to entirely support such inmate, and pay every expense of maintenance, clothing, wages, etc., incurred by the institution in his behalf. There is no check upon the growth of these institutions (which include the Nursery and Child's Hospital, for whose benefit the annual fashionable charity ball is given), the New York Infant Asylum, the Foundling Asylum, the New York Infirmary, and various church institutions) and in this direction they combine the disadvantages of both public and private charities, the recipients of their benefits having, on the one hand, no such sense of degradation as often deters persons from seeking relief in a public institution, and the managers, on the other, having no considerations of economy to force them to scrutinize with severity the claims of each applicant. The admissions to most of these institutions depend solely on the will of the managers, and there is no power that can control them except the legislature itself. For every person admitted the *per capita* allowance is to be paid. To remedy, as far as possible, the evils pointed out in relation to this class of institutions, the committee make a number of excellent practical recommendations which it is impossible to specify here.

Third. The Children's Aid Society, the American Female Guardian Society, and the Shepherd's Fold, receiving each a fixed sum per annum, secured to them by special acts of the legislature. The report gives at length the history of the management of the Shepherd's Fold by Cowiey and his wife, and comments upon it as follows: "The points to be noticed in this recital are, first, the ease with which a man, seeking only his own benefit, and quite unfit to have charge of children, obtained the passage of laws granting him city funds for the maintenance of two separate institutions; second, the culpable carelessness of the gentlemen he persuaded to act as trustees and lend their names and influence to his objects."

Fourth. The Society for Befriending Children and Young Girls, and the Five Points House of Industry, receiving a *per capita* allowance for each inmate of one dollar per week, a sum not sufficient to support the inmates without private contributions or their own labor, and, consequently, not liable to cause an increase in the size of the institutions beyond the needs of the public. The committee regards this as the right principle upon which aid from the city should be given to charities managed by private individuals, since these latter give their time and labor, and do a great service to the community by caring for persons who might otherwise become a public charge.

Fifth. Thirteen institutions of different religious denominations which receive payment from the city (two dollars a week each) for children committed by the police and civil justices. The fact that the commitments have been made by officers presumably independent in their action has, of course, been somewhat

of a safeguard against the admission of persons having no claim on public charity, but, it seems, has not proved sufficient, and these institutions, as is shown by tables given, have increased in cost at an alarming rate. It is deemed very important by the committee that some permanent method of furnishing information to the justices in regard to all children brought before them should be devised, and the appointment of one or more officers of the grade of the truant agents of the Board of Education is suggested. Another matter of great importance in regard to children committed to institutions and supported by the city is the length of time during which the right of the parent to reclaim the child shall continue.

Sixth. The Colored Home, an institution receiving its principal support direct from the city of New York, under a special act, through the Commissioners of Public Charities and Correction, who each year ask for a special appropriation for its maintenance.

Seventh. The House of Refuge, which receives no direct aid from the city treasury, but which, under special laws, draws an income from the licensing of theatres, etc., and is thus indirectly aided by the public funds. The parents of children committed to this institution, as well as one or two others mentioned, the committee think, should be required to pay for the maintenance of their children, since the penalty for neglect of parental duties now falls mainly upon the public and the child. In Great Britain during the year 1879 £18,000 was collected from parents for support of children in reformatory schools. The saving in money is, of course, a matter of importance; but the moral saving, in the increased vigilance of parents over their children, is regarded by the committee as of undoubtedly far greater value.

Eighth. About one hundred societies, which are mainly supported by private funds, but which receive, in addition, a yearly donation from the excise fund. In this class are included a large number of hospitals, infirmaries, and dispensaries. Besides the foregoing payments by the city, a certain amount is paid each year to various state and other institutions for the board of patients suffering from special affections.

Seventy-three institutions (including those under the charge of the Commissioners of Public Charities and Correction), of which statistics are given in the report, contained during the two years ending September 30, 1880, a constant population of about 22,000, and received from the public funds more than \$4,000,000 during the same period, besides about \$2,100,000 from private sources. In concluding its exhaustive report, the committee says: "The magnitude of the interest represented by the charities of the city of New York, as exhibited in the foregoing statement, must command serious attention. The great good they accomplish, the efficiency and devotedness of those engaged in this administration are admitted, and it is not proposed in this report to cripple their efforts or to discourage their zeal. It is believed that a combination of private effort with public aid is the true principle upon which to furnish the relief those institutions ought to afford. It is, how-

ever, in the direct interest of the meritorious institutions themselves, as well as of economy to the tax payers, that the system should be revised, with a view to the prevention of abuses to which it is now subject. Parents able to maintain their children should not be permitted to make them a public charge, and with this view the method of commitments must be amended. The system of public relief should not be such as to induce selfish and unscrupulous persons embark in charity as a business, and with this end in view some restraint must be placed upon the organization of societies claiming participation in the public relief funds. The public contributions towards these institutions should be within a limit, to encourage private charity, to restrain extravagance, to promote economy, and to secure the entire application of the fund to the ostensible object."

THE MASSACHUSETTS GENERAL HOSPITAL OUT-PATIENT DEPARTMENT.

A paper on the perplexing question of the abuse of free dispensaries, by Dr. Whittemore, Superintendent of the Massachusetts General Hospital, with the discussions thereon in two of the prominent medical societies, was recently published in the JOURNAL.

From the discussions it was evident that much difference of opinion prevailed in the profession as to the amount of abuse and as to the most effective remedies.

The trustees of the Massachusetts Hospital apparently agree with the superintendent that a very serious abuse does exist, and that it is worth while to make an effort to remedy it. We understand that an officer is to be employed at a considerable salary to investigate the cases of doubtful applicants. Moreover, the trustees of the hospital have distributed a circular amongst the profession of the State, and charitably disposed persons generally, and have caused a notice to be posted at the hospital. The notice runs as follows:—

On and after April 1, 1881, the Out-Patient Medical and Surgical Service will be restricted to such sick and disabled persons as are unable to pay fees. No others will be treated. This restriction is made necessary in consequence of the large and increasing number of persons applying who are not in need of charitable treatment, and whose attendance obstructs the service for those persons who do need it.

Applications for treatment must be made to the admitting officer.

The circular which has been distributed is to the following effect:—

On and after April 1, 1881, the Out-Patient Medical and Surgical Service will be restricted to such sick and disabled poor persons as are unable to pay fees, and no others will be treated. The trustees are compelled to make this restriction in consequence of the rapidly increasing attendance in this department, which already is overcrowding the resources of the hospital, and if allowed to continue will presently become unmanageable. During the year 1880 over 37,000 visits were recorded, and at the present ratio of increase the number will in a few years exceed 100,000. A large proportion of the attendance are not needy persons, requiring charitable treatment, many of them coming from a distance, some from outside the State, at expense of time and money, and interfering with the service required by poor persons who cannot afford to pay fees or fares. The duty of the hospital is to this latter class, who cannot provide for them-

selves when sick or disabled. The trustees feel that the administration of the out-patient department, under which the attendance has so rapidly multiplied, having more than doubled during the last decade, is a vicious encouragement to thrifty and well-to-do persons to depend upon charity for their medical advice, while able to pay reasonable fees — is fatal to a proper self-respect — is unjust towards the medical profession, and at best a questionable use of the limited funds of the hospital.

Members of the medical profession and other benevolent persons who have had occasion to direct sick or disabled persons to this department and may continue to do so, are requested to keep in mind the restriction herein mentioned, and to assist the government of the hospital in correcting an abuse which is injurious to all the parties to it.

If the other dispensary and out-patient services continue their present vigilance some positive beneficial results may fairly be anticipated from this step. We hope the fears, if such exist, of those engaged in medical teaching, that a deficiency of proper material for instruction will follow this effort at reform will not be realized, and that, in any case, only the most urgent necessity will be allowed to suggest the establishment of further facilities for obtaining free medical advice.

SURGEON GEORGE A. OTIS.

DR. GEORGE A. OTIS, surgeon United States Army, died on February 23d of apoplexy. He was born in Boston, 1830. Graduated at Princeton, and received the degree of M. D. from the University of Pennsylvania in 1850. He continued his professional studies for a time in Europe, and settled as a practitioner in Richmond, Va., where, for a number of years, 1853 to 1859, he assisted in editing the *Virginia Medical and Surgical Journal*. In 1859 he settled in Springfield, Mass. At the outbreak of the rebellion he entered the service as surgeon Twenty-Seventh Massachusetts Volunteers, serving until its close. In 1866 he was appointed assistant surgeon United States Army. At the time of his death he was preparing the third volume of the surgical series of the *Medical and Surgical History of the War of the Rebellion*. The surgical section of the Army Medical Museum, so noted for its completeness and value, owes much of its development to his personal efforts and supervision.

MEDICAL NOTES.

— Physicians in Boston are warned against an instrument thief. He is a man of about thirty years of age, of good address and appearance, claiming to be a medical student from Montreal in need of assistance, and desirous of collecting physicians' accounts.

— The number of medical journals created since 1679 exceeds 2500. Annual average of births twelve and a half. Death-rate not given.

— Dr. Hastings Burroughs, of the English Dispensary, Paris, writes to the *Medical Press and Circular* on the advantages of the phosphide of zinc in the treatment of locomotor ataxia, and supports his good opinion of it by several cases in which marked amelioration of the characteristic symptoms followed its use.

— Of fifteen deaths which occurred in one week

recently in London from small-pox among children under five years of age thirteen were among the unvaccinated.

— A peculiar device to terminate the chloroform narcosis is mentioned by Schirmer in the February number of the *Centralblatt f. Augenheilkunde*. He claims to have used it in his clinic for many years, and often succeeded in producing inspiratory movements when other means failed. He also employed it to induce rapid recovery, for instance, in strabismus operations, in order to test the result. The method consists in irritating the nasal mucous membrane. It has long been known, at least to physiologists, that the fifth nerve retains its sensibility longer than any part in narcosis, and that reflexes may be induced through this nerve when other irritations fail. Schirmer uses simply a rolled piece of paper, which he turns in the nose. In dangerous cases he dips the paper into ammonia. — *Medical Press and Circular*.

— Dr. Wilm, who married a Princess of Würtemberg last year, much to the annoyance of her relatives, is said, according to a correspondent of the *London Globe*, to have made her extremely happy. Having an extensive practice at Breslau, where he is trying to obtain a professorship of medicine at the university, he is ably assisted by his accomplished wife in the care of his patients, many of whom, too poor to procure the necessary remedies, are aided by the former princess, ambitious of fulfilling her self-chosen duties. She has just been confined of a daughter, whose baptism was the occasion of quite an ovation on the part of the grateful people of Breslau. Madame Wilm is not the only German lady who relinquished her princely title for the sake of a doctor, for Madame Esmarch, the wife of the famous surgical professor at Kiel, was also born in the purple. She is aunt to the young Princess Victoria of Schleswig-Holstein, shortly to be united to Prince Wilhelm of Prussia, heir to the imperial throne of Germany.

— A correspondent of the *London Medical Journal* sends the following lines, with the hope that the sentiments therein expressed will meet with an echo in many a breast which would recoil from Mr. Tenyson's "In The Children's Hospital": —

TO A PHYSICIAN.

Oh! watched for, longed for, through the weary hours
Of pain and weakness. What a gift is thine!
What a proud science, God-like and benign!
To pour on withering life sweet mercy's showers,
And on the drooping mind's exhausted powers
Like a revivifying sunbeam shine;
For thy next smile what sleepless eyelids pine!
What sinking hearts, to which the summer flowers
Can breathe no joy! How many a day
I heard thy footsteps come and die away,
And clung unto that sound as if the earth,
With all its tones of melody and mirth,
To me had naught of interest — nothing worth
The brief bright moments of thy kindly stay.

E. M. H.

— On February 5, 1881, the *British Medical Journal* reported that "the death-rate of London rose last week to 29.8 per thousand annually, and was greater than in any of the preceding fifty weeks. Deaths from zymotic diseases are considerably below the average, but the mortality from diseases of the respiratory organs was very largely in excess."

— At the Obstetrical Society of London sixty-two calculi were recently shown by Dr. Galabin, which had been removed by vaginal lithotomy from the bladder of a woman whose uterus and bladder had been prolapsed for seventeen years. After the operation the parts were replaced, and control of the bladder was soon regained.

— The importance of a knowledge of the *cuisine* of the sick room, is becoming more appreciated daily. A course of lectures and demonstrations on the subject of cookery has been commenced in the Edinburgh School for the benefit of medical students and practitioners. The course was inaugurated in the large theatre of the Edinburgh Royal Infirmary on Saturday, January 22d, under the supervision of Professor Fraser, who introduced the teachers. In doing so he spoke of the importance of medical men thoroughly understanding the preparation of suitable food for invalids, and paid a just tribute to the Edinburgh School of Cookery for the good work it has already achieved towards other members of society. The teachers then proceeded to prepare and cook certain articles, and these, when ready, were submitted to the critical and gustatory examination of the audience. The demonstration was successful, and earned a hearty vote of thanks. The second demonstration followed on the succeeding Saturday.

— Ladies with beards will be glad to hear of a remedy. Mr. Lawson Tait reports a case where the beard fell off after the application of a galvanic pessary. — *Canada Medical and Surgical Journal*.

— Frank Buckland, the English physician and naturalist, who has been the object of numerous obituary notices in the various English medical journals, was the discoverer of the body of John Hunter in the vaults of St. Martin's Church in 1859.

— Dr. Reginald Southey, of London, will deliver the Lunnleian lectures this year. The subject will be Bright's disease.

WASHINGTON.

— On February 18th, Hon. Benjamin W. Harris, of Massachusetts, delivered a speech in the House of Representatives on the joint resolution relating to color-blindness and visual acuteness in persons employed in the navy and merchant marine. He alluded to petitions relating to the subject which had been previously presented, and which were signed by a few names representing great scientific and literary attainment, high standing and reputation in the country. Dr. B. Jay Jeffries, as the head petitioner, was heard with much satisfaction by the committee on naval affairs. He found no difficulty in satisfying the committee of the existence of color-blindness to a dangerous degree, for the committee were able to furnish him from their number two examples of decided color-blindness. The committee unanimously and promptly agreed that the subject deserved immediate and effective action on the part of Congress. In their report they quote freely from Dr. Jeffries's Manual, railroad experts, reports of the Marine Hospital Service, and the article by Lieutenant Schroeder (United

States navy) on collisions at sea, in the *United Service* for August, 1880; and in their appendix give a very useful summary of army, navy, railroad, and state legislative action. The bill in question looks to "a general law of control in the navy and merchant marine of color-blindness and visual acuteness, and the agreement by an international commission upon definite and uniform standards of testing these necessary qualifications." Mr. Harris concludes by suggesting that the several governments taking part in this international commission should not send color-blind delegates, and to "show the natural possibility of it" instances a commission appointed by the British government a few years since on lights, buoys, and beacons; there were five members: one was so color-blind that he could not distinguish a red light from a dull white one, another was abnormal in his perception of colors. An occasional clerk of the commission was once found writing with red ink, believing it to be black.

— On the final passage of the general appropriation bill for the District of Columbia in the United States Senate, February 18th, Senators Edmunds and Withers commented strongly on the large number of contributions to public charities, and the necessity for a suitable private provision of public hospitals absolutely under public control. Senator Beck was satisfied "that we ought to have a general hospital, and ought to have it as soon as possible, and that some well-selected site ought to be had, no matter what it costs, for Washington is worse provided for general hospital purposes than any city in America."

MEDICO-LEGAL.

— Supreme Court of Illinois. Bill brought by Henry Olin to restrain John Bate and Edward Osborne from using the name or title of complainant, or any name so like it as might mislead the public to his prejudice. Complainant is a physician, and has practiced his profession for many years, but gives particular attention to diseases of the ear and eye. His office is in the city of Chicago, where he has practiced since 1870. It is alleged defendants are physicians, giving attention to chronic and sexual diseases of men and women; that they advertise their business in the newspapers, and that they have published pamphlets or books that tend to corrupt public morality. It is also charged the business conducted by defendants is disreputable; and because it is believed by many people in Chicago and elsewhere that complainant is the "Dr. Olin" mentioned in the advertisements and books published by defendants, he insists his professional reputation is impaired, and that he is by the acts of defendants, under the name of "Dr. Olin," brought into disrepute as a physician. An amendment to the bill made by leave of court sets forth that in 1875 defendant Bate applied for admission as a student to "Burnette Medical College," of the faculty of which institution complainant at the time was a member, and that defendant, in consideration that complainant would consent to his admission, agreed to abandon the fictitious name of Olin, and engage only thereafter in a reputable business.

On the understanding and agreement alleged, complainant assisted in the graduation and granting to Bate a diploma, which, it is alleged, he could not have obtained without the consent of complainant. In the superior court the bill was dismissed for want of equity. The case was carried to the supreme court on appeal.

Scott, J. (*After stating the facts.*) No importance need be attached to the agreement set forth in the amended bill, that defendants would abandon the use of the fictitious name of "Olin," if complainant would consent to the admission of Bate to the medical college, and would assist in the graduation and granting to him a diploma, for the reason that a contract of the nature of this one insisted upon is of such doubtful propriety that equity will not lend its aid to enforce it. The granting of diplomas to students in colleges ought not to be made the subject of private contracts with individual members of the faculty, for personal advantage to themselves. They should only be granted on account of the moral standing of the students, and on account of their proficiency in the studies taught in such institutions. There can be no pretence that defendant Osborne ever assumed the name of "Olin." The utmost he did was to assist Bate in his professional duties, and that he did in his own name. Nor is there any proof that Bate ever assumed the full name of complainant. The proof shows that before he came to Chicago to reside he assumed the name of Andrew G. Olin, and since then has been known as "Andrew G. Olin," "A. G. Olin," and "Dr. Olin" in his profession. But that is not complainant's name, and never was. His name is "Henry Olin." Defendant has never advertised himself as "Henry Olin," and, so far as this record discloses, never represented to any that he was "Henry Olin." Their professions are totally distinct as to the diseases they profess to treat. Persons desiring treatment for diseases each profess to cure would not be likely to call upon one for the other unless grossly careless. Such mistakes would be of rare occurrence, and it would be absurd to say that the few that might occur would amount to "irreparable injury" to either party. Whether the business defendants are pursuing is disreputable or not cannot be made the ground of equitable relief in favor of complainant. Offenses against public morality, where any exist, can be more appropriately redressed in the name of the people, against the body of whom the offense is.

Complainant complains that he is subjected to embarrassment and perhaps disgrace on account of the conduct of defendant in assuming a name nearly like his own. Should that fact be conceded, but which does not appear in any proof, he has elected of his own volition to expose himself to it. Bate had assumed the name under which he chose to transact his professional business, and located in Chicago long before complainant came there to reside. No equitable considerations, therefore, arise in favor of complainant for whatever embarrassments he may be subjected to, if any come to him from his own selection of a location in which to practice his own profession. Judgment affirmed. — *The Reporter.*

Miscellany.

VACCINATION AND REVACCINATION ONCE AGAIN.

MR. EDITOR. — I have been much interested in the articles on vaccination that have appeared in the last three numbers of the JOURNAL, and have been rather surprised that your first editorial did not call forth some statement, at least, from those who have authority to speak on the subject. I refer, of course, to our Board of Health. Inasmuch, however, as the *only result* (excepting, of course, the general public excitement and the consequent rush for vaccine matter) has been the article by "Deltoid," which takes the ground that the necessity for frequent revaccination is not to be taken as a generally acknowledged and proved scientific fact, there is one point to which I should like to call your attention. I will not stop to investigate whether the existing state of affairs in Boston and the surrounding country is such as to warrant such a note of alarm as was given in your issue of the 10th inst., especially alarming from the fact that it was sounded from the editorial sanctum, and as such was reproduced immediately in a daily paper, as that is a matter on which argument is impossible. As a specimen of ingeniously twisting statistics to prove a desired point the use that is made of Marston's table in the answer to Deltoid is a most striking one. From this table it appears "that whereas the average mortality of post-vaccinal small-pox was five or six per cent., that of second attacks of small-pox was as high as nineteen per cent.," and this is advanced as proving that the protection afforded by vaccination and revaccination was greater than that accruing from antecedent small-pox. It does not, of course, prove anything of the sort, but simply shows that in cases where the disease attacks a person a second time the ratio of mortality is high. It is a perfectly supposable case that while only one person in ten thousand ever has small-pox twice, the fatality in the cases that do may be very great; in fact, it might be that every such case resulted fatally, and in accordance with the reasoning laid down, in spite of the fact that only one person in ten thousand ever had small-pox a second time, we should have to assume that the fact of having had the disease gave no immunity at all. In order to get any statistics bearing on the question, a certain number of persons who had had the disease and the same number who had been revaccinated should be exposed to the same chances of contagion, and then some valuable evidence might be obtained.

But what I do want to say is, that in such an article the omission of even a reference to the very thorough work in the way of vaccination and *revaccination* in this city in 1872-73 is inexcusable, not only as ignoring very good work started by the city government, and taken up and completed by our able Board of Health, but as omitting to speak of a very important factor in the stamping out of the epidemic of that period, and what is more to the point as failing to take advantage of one of the strongest possible arguments in proof of the correctness of some of the ideas advanced.

Your article rather takes the ground that the idea of the necessity of revaccination is a *new one*, or at least one that is not generally appreciated in this community. In 1872, when the disease acquired the proportions of an epidemic, each ward of the city was put under the charge of an alderman, who appointed two

physicians to see to the vaccination of the inhabitants. As far as I know the appointments were without exception proper ones. The men were of course drawn from the younger members of the profession, but they were all, I believe, properly educated regular practitioners. I can only speak from personal knowledge of one ward, but in that case the alderman selected men who had been recommended by physicians whose judgment he had confidence in, both of the appointees being personally entirely unknown to him. The work was certainly most thoroughly done, and on the establishment of the Board of Health it was carried on still farther, and to a certain extent the ground was gone over again. I do not mean to say that every inhabitant of the ward was examined, but I do say that in those streets occupied by the ignorant and perhaps vicious classes, of which the ward in question was by no means destitute, every house was not only visited, but every dweller in it was either seen or ordered to report at the police station in the evening, and in some way a very large proportion of them were subjected to an examination.

Naturally the greater part of this work was revaccination. The proportion of persons found who had never been vaccinated was almost infinitesimal. The exact line to be drawn as to what cases needed revaccination and those that did not varied, of course, according to the ideas of the individual physician (I mean until the Board of Health took charge of the matter), but I think it safe to say that the rules for guidance generally adopted were, to say the least, fully as stringent as those hinted at in your article. Under the Board of Health isolation was insisted upon, and in connection with it the revaccination of everybody in the house and vicinity. I have no doubt myself that it is on account of that general, thorough, and intelligent work of that time that the marked immunity of Boston since has been due. As a matter of course that immunity is not going to last forever, and if everybody has forgotten or never learned the lesson taught in 1872-73 there might be some cause to show the matter up. But with the bulk of the profession having that experience to guide them, with a Board of Health, or its most important part, at least, that began its work at that time, it does seem to me that there is no occasion for alarming the public. It is not at all with the idea of denying or combatting the statements made in your articles as to the necessity of proper revaccination that I have written what I have, but that I believe that this necessity is generally admitted and acted upon by most intelligent practitioners, and that I do not believe it advisable under the present circumstances to start a popular scare. And in conclusion I would say, with all due respect, and perhaps your adoption of the slang of the prize ring will induce you to pardon the expression, that to one who went through the epidemic of 1872-73 your editorial of the 19th inst. forcibly recalls the homely old adage of "teaching your grandmother to suck eggs." Yours truly,

G.

CASE OF PROTRACTED GESTATION.

MR. EDITOR,—The subject of this sketch is an American, a resident of Warren, Rhode Island, thirty-five years of age, and the mother of four children. She always enjoyed the average health of her sex, and nothing unusual occurred in either of her former preg-

nancies, nor in this one, except the lengthened period of gestation.

The termination of the last menstruation previous to the birth of the child was July 28, 1876. The husband left home August 1st, four days after, and did not return until November 28th, nearly four months. Symptoms of pregnancy in the mean time supervening, and quickening occurring at the usual time, she expected to be confined by the 1st of the following May, but there were no signs of labor until June 20th, when she was successfully delivered of a healthy male child, bearing as strong a resemblance to his father as you often see. The child weighed twelve and three quarters pounds, and presented the general appearance of one, two, or three months of age.

In case conception took place July 31st, the time of the last sexual intercourse prior to the husband's departure, the labor terminated on the *three hundred and twenty-fourth day of gestation*.

If there are other well-authenticated cases where the term of healthful gestation has exceeded the *nine calendar months and fifty days*, as this one did, there are none certainly with a more reliable and trustworthy record. The data are correct, and the woman's veracity and virtue are not to be called in question.

J. M. MERCHANT, M. D.

WARREN, R. I., February 24, 1881.

REVACCINATION.

MR. EDITOR,—A "vaccination point" which occurs to me, and to which I think some importance may be properly attached, is this: We know from past experience that the instant we have small-pox among us people (especially those merry and devil-may-care dogs who laugh at vaccination and "prefer small-pox and done with it") immediately roll up their sleeves and demand our attention at once. Under these circumstances the "boom" in vaccine lymph sets in, and as the demand increases we begin to obtain very peculiar results from its use. In some cases one might almost imagine that the points used had been dipped in the secretion of a hard chancre,—so obstinate and indurated are the ulcerations produced. In others our suspicions are directed towards the inoffensive mucilage bottle. I think if we proceed now to quietly vaccinate such of our patients as we think require it, we may avoid the results mentioned above (which are inevitable if the disease visits us), and obtain in many cases what we seek—an

UMBILICATED VESICLE.

ACTIONS FOR LIBEL.

BESIDES the action pending in the Court of Queen's Bench against Dr. Hoggan and the publisher of the *Medical Press*, there are two others likely to excite much interest in medical circles, which will probably be disposed of in the after-sittings of next term in Dublin, and in the County Assize of the same date for Tyrone. In the first of these actions, our contemporaries, the *British Medical Journal* and the *Cork Constitution* are to be the victims of actions for libel on the part of Mr. James Crawford, the Cork schoolmaster, whose unwarrantable attack on Dr. H. M. Jones in regard to the use of pilocarpine for the treatment of his child, who died of scarlatina in the Cork Fever Hospital, will be fresh in the minds of our readers. Our contemporaries, in common with ourselves, and

every other medical journal of any character in the United Kingdom, criticized the charges against Dr. Jones, and animadverted on Mr. Crawford's conduct, and the vindictive manner in which the attack on Dr. Jones had been pursued. Since the decision, which exonerated Dr. Jones was delivered by the governors of the Fever Hospital, Mr. Crawford, whose mental balance would seem to have been entirely upset by his family bereavements, has devoted himself to the posting of the dead walls of Cork with placards, which were none the less injurious to Dr. Jones, because they were obviously the emanations of a prejudiced mind, and now he seems to have succeeded in inducing a solicitor to take his fancied grievances into the courts of law. While the case is *sub judice* we can only express our hearty sympathy with the *British Medical Journal*, the *Cork Constitution*, and especially with Dr. Jones, in the persecution of which he is the victim. The second action is one for a libel upon Dr. Kinkead, professor of obstetrics in the Galway College, said to

have been contained in a letter addressed by Dr. Valentine Browne, surgeon to the County Infirmary, to Dr. Pye, professor of anatomy in the same college. Dr. Kinkead had, for several years, delivered clinical lectures, with consent of Dr. Browne, in the County Infirmary. Dr. Colahan had been subsequently admitted to the same function, an arrangement being come to with Dr. Browne on the subject of fees. This arrangement Dr. Browne has subsequently repudiated, and the alleged libel is contained in a letter in which he sets forth his reasons for excluding Dr. Kinkead in terms which that gentleman considers actionable, and, accordingly, he has brought his suit in order that his professional reputation may be set right. Last week the question whether such a communication, assuming it to be libellous, was privileged, was argued before the court of exchequer in Dublin, and judgment was given against Dr. Browne, so that the case will probably be heard on its merits next term.—*Medical Press and Circular*.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 19, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under five Years.	Percentage of Deaths from

Deaths reported 2856 (no return from Buffalo); 1074 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 595, lung diseases 445, consumption 407, diphtheria and croup 235, scarlet fever 105, small-pox 65, typhoid fever 41, erysipelas 36, diarrheal diseases 36, cerebro-spinal meningitis 22, measles 18, malarial fevers 15, whooping-cough 14, puerperal fever six, typhus fever one, chicken-pox

one. From *typhoid fever*, Philadelphia nine, Chicago, Baltimore, and Pittsburgh four, New York and Cincinnati three, Boston, District of Columbia, and Lowell two, Brooklyn, St. Louis, New Orleans, Milwaukee, Charleston, Worcester, Chicago, and Westborough one. From *erysipelas*, New York 10, Brooklyn six, Boston four, Philadelphia, Cincinnati, and Cambridge two, Chicago, Baltimore, Milwaukee, Providence, New Haven, Worcester, Fall River, Springfield, Somerville, and

Fitchburg one. From *diarrhoeal diseases*, New York 10, New Orleans eight, Philadelphia and St. Louis four, Chicago three, Baltimore, Cincinnati, Pittsburgh, Providence, Charleston, Lawrence, and Northampton one. From *cerebro-spinal meningitis*, New York six, Lawrence five, Chicago three, Philadelphia and St. Louis two, Chelsea, Fitchburg, Attleborough, and Clinton one. From *measles*, Boston eight, New York four, Baltimore, Cincinnati, Milwaukee, Worcester, Somerville, and Newton one. From *malarial fevers*, New York seven, St. Louis, New Orleans, and District of Columbia two, Brooklyn and Chicopee one. From *whooping-cough*, Chicago three, New York, Philadelphia, and Baltimore two, Brooklyn, Boston, St. Louis, Cincinnati, and Worcester one. From *puerperal fever*, St. Louis and Newburyport two, Baltimore and Pittsburgh one. From *typhus fever*, Chicago one. From *chicken-pox*, Spencer one.

Sixteen cases of small-pox were reported in Brooklyn; 13 in Chicago; nine in Pittsburgh; one in Holyoke; scarlet fever 39, diphtheria eight, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,095,848 (population of the State 1,783,086), the total death-rate for the week was 22.17, against 20.97 and 23.39 for the previous two weeks.

For the week ending January 29th, in 149 German cities and towns, with an estimated population of 7,855,534, the death-rate was 27.7. Deaths reported 4180; 1851 under five; pulmonary consumption 568, acute diseases of the respiratory organs

518, diphtheria and croup 170, scarlet fever 75, whooping-cough 67, typhoid fever 54, measles and röteln 42, puerperal fever 32, small-pox (Königsberg 5, Lübeck, Berlin) seven, typhus fever (Stargard) one. The death-rates ranged from 19.6 in Stuttgart to 42.4 in Münster; Königsberg 29.1; Breslau 31; Munich 29.8; Dresden 25.3; Berlin 25.3; Leipzig 24.4; Hamburg 28.9; Hanover 19.5; Bremen 20.4; Cologne 26.6; Frankfurt 22.8; Strasburg 30.4.

For the week ending February 5th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 28. Deaths reported 4092; acute diseases of the respiratory organs 606, whooping-cough 102, scarlet fever 70, small-pox (London) 54, measles 49, fever 41, diarrhoea 30, diphtheria 20. The death-rates ranged from 20.3 in Newcastle to 37.2 in Manchester; Sheffield 22; Birmingham 25; Leeds 28.8; Bristol 30.8; Liverpool 36.5. In Edinburgh 19; Glasgow 34; Dublin 45.7.

In the 20 chief towns in Switzerland, for the weeks ending January 29th and February 5, estimated population 522,856, there were 42 and 38 deaths from acute diseases of the respiratory organs, diphtheria and croup 18 and 14, diarrhoeal diseases 17 and seven, typhoid fever 10 and nine, whooping-cough nine and two, small-pox five and four, scarlet fever two and none, measles two and one, puerperal fever one and none.

The meteorological record for the week in Boston was as follows:—

A CLINICAL LECTURE, WITH CASES, ON FOREIGN BODIES WITHIN THE EYE, AND THE ELECTRO-MAGNET AS AN AID TO THEIR DETECTION AND REMOVAL.¹

BY MACDONALD MCHARDY, F. R. C. S., ED.,

Professor of Ophthalmology and Ophthalmic Surgeon to King's College Hospital, London.

GENTLEMEN,—To-day, I wish to call your attention to the most serious class of injuries to which the eye is subject. Foreign bodies buried in or within the organ of sight, are most fruitful sources of blindness, not only to the eye originally hurt, but to its fellow, through sympathetic mischief. You may take it as an established truism that every eye whilst lodging a foreign body is threatened with destruction by its tenant. Neither the position nor the size of the foreign body negative this, though both are matters of very material importance in estimating the degree of serious gravity attaching to such a case.

Moreover, you must recollect that, as I have just hinted, the danger is not confined to the injured eye alone, the risk of blindness being shared by its fellow. Sympathetic ophthalmia, an affection indefinitely deferred, insidiously developed, obstinately progressive, and deplorably blinding, often attacks the fellow of an eye rendered useless by a penetrating foreign body, which may be located in any part of the globe.

You may judge, therefore, something of the importance attaching to the detection and removal of such foreign bodies, and the responsibility incurred by one who, undertaking to treat an injured eye, does not do his uttermost to arrive at a correct diagnosis regarding the presence or absence therein of a foreign body.

The investigation of these cases should be conducted by the aid of focal illumination, the pencil of light being thrown from every direction on to every visible surface of the globe, so that the position of any superficial indication of a wound may be fully lighted up and searched for by the aid of a magnifying glass.

For this purpose the two object glasses commonly supplied in the case with many of the hand ophthalmoscopes will answer admirably; but if, as I believe is the lot with most of you, your ophthalmoscope be one of the most excellent *multum in parvo*, practically efficient, simple, and strictly economical instruments,² which I recommended you to procure, then using the single object glass thereof for concentrating the light, you will need a second as a magnifier. This may be an ordinary pocket lens, one of twenty dioptries from the trial case, a common burning glass, or watch-maker's loupe, which I mention lest the possession of only a single object lens, with your ophthalmoscope, should be conjured into an excuse for the inefficient examination of these cases. This scrutiny, with the two lenses, of the superficial parts must be extended to the anterior chamber and surface of the iris. Here, let me remark on the importance of conducting the examination thus far, before applying any mydriatic to dilate the pupil, as it happens at times that foreign bodies which penetrate the cornea, or corneo-scleral junction, remain partially imbedded in the tract along which they passed, whilst projecting into the anterior chamber, where the

interposition of the iris may serve to screen the capsule of the crystalline lens from injury.

In other instances the foreign body may be so situated, loose in the anterior chamber of the aqueous humor, that it would be liable to fall through a dilated pupil into the posterior chamber, out of sight, behind the iris. Further, the smaller the pupil, the greater the assistance the iris may lend to the safe extraction of a foreign body projecting into or loose in the anterior chamber, as you will be able to infer from the two following cases, the narration of which will show you how similar ones may be brought to a successful issue:—

A clerk, aged thirty-three, whilst winding a spring skeleton clock, the cord of which was frayed, was struck by a fragment, eight mm. long, of the very fine brass wire composing the frayed cord, which had broken. I immediately examined the injured eye and could see one extremity and some seven mm. of the foreign body lying, perfectly straight, within the transparent cornea. One end of the wire was concealed beyond the corneal margin; the other was lying beneath the external surface of the cornea, close within the spot at which it was evident the missile had entered. It appeared that a portion of the middle of the fragment was within the aqueous chamber, whilst either end was held imbedded in corneal tissue, and this proved to be the case. Having further exposed the visible end of the wire, by a section over it, into, but not through, the cornea, I seized the hard body with iris forceps which did not grip sufficiently to assist its withdrawal by direct traction; so I attempted to turn the freed extremity of the wire forward, anterior to the corneal surface, to admit of its being gripped by dissecting forceps. But this manœuvre had to be abandoned, as the centre of the wire recoiled against the iris when the extremity was prized forward. I next made a puncture through the cornea, immediately opposite that portion of the wire which was in the aqueous chamber, about midway between the centre and margin of the cornea in its upper and inner quadrant; inserted a Tyrrell's hook through the puncture, beneath and around the wire, so that when the hook was withdrawn the portion of wire, bent like a hairpin, came with it. A small portion of iris, which was dragged through the wound between the ends of the wire, was caught in forceps and removed with scissors after sufficient had been withdrawn to obviate the risk of any remaining impacted in the corneal wound. Under the use of atropine and a compress the eye recovered, with no greater impairment of vision than resulted from the small eccentric corneal scars.

On another occasion I saw an engineer, aged twenty-two, with a large-sized grain of gunpowder lodged between the cornea and upper part of the iris, the result of an accident on the afternoon of the previous day. There was intense ocular congestion, great photophobia, and discoloration of the aqueous humor. I made a large upward section in the corneo-sclero junction, by transfixion with a Graefe's knife, taking care not to displace the foreign body by the passage of the blade. A pair of iris forceps, with points bent at right angles to the shaft, were introduced well into the anterior chamber, as widely open as the section would permit, and then withdrawn closed, so as to have in their grasp the foreign body wrapped around with a large piece of iris, which I cut off with scissors. A simple compress was applied, and nothing occurred to hinder complete recovery.

When the probability of the presence of a foreign body anterior to or in the iris has been excluded, the pupil should be dilated to its widest by the application of a solution of atropine (four grains to one ounce).

For these cases it is better to make the solution with castor oil rather than water, as patients with corneal wounds appreciate the lubrication afforded by the thick oil. The search by focal illumination has next to be carried through the wide pupil into the posterior chamber of the aqueous. Therein a foreign body may be discovered resting on the anterior capsule of the crystalline lens, in a position which was completely concealed by the iris prior to the dilatation of the pupil. Though a missile can but very rarely penetrate to such a position without piercing the capsule of the lens, and occasioning opacity thereof by the admission of the aqueous, yet

¹ Delivered January 31, 1881.

² Wecker's compounded metrical refraction ophthalmoscope, by Crété, Paris. Price forty francs, or thirty-five shillings, by Pickard and Curry, London.

it has happened. A wound of the anterior capsule of the lens does not invariably lead to either immediate or complete opacity thereof, though both are its commonest consequences. Cases are on record, and I have met with one such, in which a particular section of an injured lens became opaque whilst the remainder retained its normal transparency. Still rarer cases are those in which it is reported that foreign bodies buried actually in the substance of a transparent lens have become encapsuled and surrounded by a but limited opacity. Of these I have no personal knowledge. However, you must not be misled by the abundant reports of eyes remaining quiet for long periods whilst tenanted by a foreign body, for such come to crowd the literature of the subject, through being exceptional in the practice of ophthalmic surgeons, who, having to treat vast numbers of eyes with foreign bodies in them, would not report the great many that demand enucleation, whilst too pleased to record the few which furnish the exception needed to prove the rule. Moreover, it is noteworthy that very many of the reported cases in which eyes have quietly lodged foreign bodies for several, upwards of twenty, and in one instance twenty-seven years, have attracted attention by the mischief they have finally occasioned. Very frequently a useless, irritable eye is enucleated, and the surgeon receives no clue to the character of the original injury until a microscopic examination of the interior of the globe reveals a foreign body.

Individual experience and the statistical investigation of recorded cases alike show that foreign bodies are least tolerated when situated in or upon the ciliary processes or in contact with the choroid and retina, and are most tolerated in the vitreous or aqueous chamber. They may remain lodged in an old lens, causing complete cataract thereof, and give no further evidence of their location until discovered in the lens after its extraction. The larger a foreign body be, *ceteris paribus*, the more destruction its presence in an eye will work. Dense substances, such as chips of metal or glass, are usually less mischievous, excepting that they often penetrate more deeply than splinters of wood or thorns, which may create additional irritation by swelling with the absorption of moisture.

Every blind eye, reasonably suspected to contain a foreign body, should be promptly enucleated, whether it be or be not painful. This is more imperatively necessary with patients of the less educated class, for such will so superstitiously treasure an eye, though it be blind, that, despite every warning from the surgeon, who probably advised enucleation at the time when an accident spoilt the sight, they will seek advice and conceal the truth from a strange doctor when sympathetic mischief arises.

I had an example of this during the present month at the Royal South London Ophthalmic Hospital. Happening to be there on one of Mr. Morton's days of attendance, he called my attention to some irritation symptoms in the single organ of vision of a young child, whose opposite eye was shrunken, and suggested that it was due to sympathetic ophthalmia. The mother blandly remarked to me, "Oh, sir, you remember the child you took so much trouble with, when that eye was blinded two and a half years ago, and I ain't brought the child to you since, cos you said directly she suffered anything with either eye the blind one ought to be took out." In this case a foreign

body had penetrated the sclerotic, and occasioned bleeding into the vitreous chamber so as to frustrate any immediate search therein. When the extravasated blood became sufficiently absorbed I could see nothing of the missile, but recognized distinct evidence of its having traversed the whole width of the vitreous, and was therefore led to hope that its momentum had been sufficient to carry it, not only into and across but also out of the globe, which I was loth to enucleate prematurely in a young child, as the subsequent contraction of the parts would prevent the wearing of an artificial eye, which might be fitted if the globe were enucleated a few years later. Mr. Morton enucleated the globe; it contained a small foreign body surrounded by firm exudation material, and lying at a point behind the ciliary processes, to which it had rebounded from the inner surface of the eye.

Having recommended you to enucleate in such cases, you will be right if you infer that I hold the operation of optico-ciliary neurotomy in no favor; indeed, I believe that, unless speedily abandoned, its introduction as an alternative for enucleation must result in the destruction by sympathetic ophthalmia of many eyes which would never have been exposed to the danger thereof, but for a misplaced confidence reposed in an operation which can offer no advantages compensatory to a diminution of the almost absolute safety securable by timely enucleation.

The following case, which is recorded in the ninth volume of the Clinical Society's Transactions, will serve to direct your attention to very many of the points associated with the subject under consideration, and records the occasion which led me to first apply electro-magnets for the treatment of iron or steel bodies within the eye. It is, moreover, illustrative of the commonest cause of such injuries, and the happy issue which may attend your best efforts to avert their dire consequences.

David B., aged thirty-one, employed in a woodworking-machine shop, came under my care, at the Royal South London Ophthalmic Hospital, in consequence of an injury to his left eye, caused by a chip flying from either a steel tool or the hammer with which he was striking the tool.

I saw him first on July 4, 1877, twenty-four hours after the accident, when commencing iritis was indicated by slight ciliary congestion and moderate discoloration of the iris. An altered reflex from a portion of the cornea, below and external to the centre, indicated where the steel chip had impinged. Before dilatation of the pupil no lenticular opacity could be detected, and the ophthalmoscope revealed nothing abnormal in the vitreous. The tension was normal, there was but insignificant tenderness. He stated that the eye was far easier than it had been on the previous night, and that he did not wish to remain in the hospital. Accordingly, as he had presented himself at the hospital just before my departure, I prescribed some atropine drops, two grains to the ounce, and directed the patient to keep his eyes shaded until the next day, when he was to be seen by me again.

On July 5th, patient said that he had no pain in the eye. The congestion had diminished since the previous day. The pupil was widely dilated, vision equaled twenty fortieths; the corneal surface was almost normal. But there was a shining, sharply-defined opacity, evidently a fragment of metal, upon the anterior surface of the lens, occupying a situation downwards and inwards from its centre. The lens was perfectly transparent, except at the small area hidden by the chip, which was a narrow, flat strip, about one fourth as wide as it was long, and in length about equal to one fifth the corneal diameter. The foreign body, lying in the direction of the downward and inward meridian of the cornea, had its peripheral end nearer to the margin of the dilated pupil than its other extremity was to the centre, and thus occupied a position which explained how it had been concealed prior to the use of atropine. Reluctant to deal at all precipitately with such a case, I enjoined absolute rest for the patient, took him into the hospital, and con-

tinued the use of atropine. From the situation and shape of the chip, if left alone, it was almost certain sooner or later to gravitate down behind the iris and lead to destructive mischief in one or both eyes; hence its removal was imperative. I recognized the possibility of the lens capsule being wounded, notwithstanding the continued transparency of the lens, for possibly the chip by its very presence was plugging a laceration in the lens capsule, and thus excluding the aqueous humor. But I could not feel sure that the lens capsule was so damaged as to necessitate the formation of cataract. I was loth to subject the eye to the dangers which attend the extraction of a transparent lens by the scoop, and could not feel that such a measure would insure the removal of the foreign body.

As the effect of mydriatics diminishes as the aqueous escapes, it would have been very difficult, if indeed possible, to keep the foreign body in view during an attempt to dislodge and secure it with forceps, and if, subsequently to effecting its removal thereby, the lens had become opaque, it would have been impossible to decide whether the original injury or my manipulations had induced the cataract.

Confronted with these difficulties, it occurred to me that a magnetic spatula would meet the requirements of the case, for thereto I could attach the chip, and watch its movement, if only a needle were matched to the spatula, so that the latter would plug the puncture made by the former, and thus prevent a loss of aqueous and diminution of the pupil.

These conditions would have been equally well fulfilled either by a permanent or an electro-magnet; but with the former I foresaw this danger, that the chip, in jumping towards an approaching magnet, might, by some sharp edge, lacerate the capsule. On this ground an electro-magnet seemed preferable, as it could be applied to the chip before any attractive power was called into play; and this power could be interrupted at pleasure, during the manipulations, so that any undesirable position of the fragment, with reference to the spatula, might be altered before extraction was commenced.

Messrs. Weiss made the electro-magnetic spatula, which I exhibit, and which, when connected with a six-celled Snee's battery, seemed likely to fulfill the indications of the case.

The instrument will be seen to consist of a straight piece of soft iron wire, four mm. in diameter, having one of its ends, for a distance of 15 mm., dressed down to form a spatula of perfectly uniform stoutness, with a smooth, blunt, flat point, and having coiled upon it six layers of very fine insulated copper wire, so that the coil extends over some three cm. of the iron wire from the spot where it is reduced to the spatula gauge. This, when connected with the above-named battery, lifted, by its spatula point, a three-quarter-inch iron tack.

I related the particulars I have just mentioned to my colleague, Mr. Brudenell Carter, who then kindly saw the case with me, and suggested that, before introducing the spatula, it would be well to try what traction, if any, a powerful magnet held in front of the cornea might exert upon the chip—a suggestion so practical that I was startled to think it had not sooner occurred to me.

On July 6th, the patient being seated in a chair, I held before his cornea this powerful electro-bar magnet (one ten inches long and an inch in diameter, coiled with four layers of stout insulated wire, and connected with two pint Grove's cells), and gradually approximated one of its poles to the eye, until, when they were about four inches apart, the chip sprang from the lens to the inner surface of the cornea. Thereupon the magnet was withdrawn, the chip fell into the anterior chamber; the patient was placed upon a couch, ether was administered, and an incision was made, through which the chip was evacuated, and a small piece of iris, which prolapsed, was excised.

Immediately the chip left the surface of the lens it revealed a patch of opacity precisely of its own magnitude, and it was therefore evident that complete cataract might be anticipated. This followed, and the injured lens underwent absorption without any inflammatory reaction being produced. Atropine was applied until the absorption was completed, and the patient has normal distant vision with a lens of twelve dioptries, and reads No. 1 of Jaeger's types with a lens of fifteen dioptries.

This case aroused my desire to ascertain the fullest extent to which electro-magnets could be usefully employed under analogous circumstances, at a time when nothing but patient experiment offered any hope of deciding what form or strength of electro-magnet might be most advantageously applied, and I became convinced that it was an error to suppose that by greatly augmenting the attractive power of a strong magnet its influence on a minute particle of iron is not

increased. This hypothesis demanded contradiction on account of the frequency and confidence with which it was announced, notwithstanding that it would seem to be disproved by the single fact that, in accordance with a certain ratio the more powerful a magnet is, so much greater is the distance at which it will attract an iron filing.

Immediately after the occurrence of this last case my attention was directed to a paper by Dr. McKeown in the *Dublin Journal of Medical Science* for September, 1876, wherein he narrates how he has successfully used permanent magnets for the diagnosis and treatment of cases of steel and iron within the eye.

Seeking enlightenment on the subject of powerful electro-magnets at a large telegraph cable manufactory, I found that the employees there, when struck in the eye by a chip of iron or steel, instead of seeking the aid of a reputedly dexterous mate, were in the habit of widely separating the eyelids and approximating the injured organ to the pole of a colossal electro-magnet, with the commonest result that the chip, no matter how small, left the cornea. The *British Medical Journal* for July 17, 1880, gives the following quotation bearing date A. D. 1745: "There was one in Salisbury, who had a piece of iron or steel stuck in the iris of his eye. The person was in very great pain, and came to me. I endeavored to push the iron out with a small spatula, but could not, and then applied a loadstone to it, and immediately it jumped out." Thus, clearly, there is no novelty about the application of magnetic traction to the extraction of iron or steel chips from the eye. The Salisbury case reads as if the piece stuck through the cornea rather than in the iris. This, too, I think the more probable as it appears impossible for a foreign body to remain sticking fast in the iris alone, if you consider the character and constant action of that muscle. Whenever a case of injury to the eye presents itself with a history that suggests the possible presence of a foreign body, no time must be lost in carrying out the examination, as I have just now described, and, if necessary, supplementing that by a most rigorous ophthalmoscopic search through every exposable part of the globe's interior. For such injuries are most liable to be quickly followed by loss of transparency in the media, either through bleeding or inflammatory exudation, and then ocular evidence of the chip is forbidden. Such a condition is too often present when the case first comes under the surgeon's notice, and then if there is a possibility of the foreign body being either iron or steel, permanent, or, better still, electro-magnets may render most material assistance, both in its diagnosis and extraction. You will be able to judge of this from the notes of the case to which I briefly referred at the close of my contribution to the ninth volume of the *Clinical Society's Transactions*, as follows: "I have succeeded, by the aid alone of an electro-magnet held in front of the cornea, first in diagnosing the presence of, and then in extracting, through the track by which it entered, a fragment of steel, measuring two by five mm., which had been imbedded posterior to the iris for forty-eight hours, during which time the wound of entrance and the pupil had alike become closed with lymph."

Here is the chip in question and the electro-magnet which extracted it is the same which worked so happily in the case I have just narrated.

The patient, a blacksmith, aged fifty-three, was seen twenty-

four hours after receiving a blow on the eye by a chip, which flew from his work when he was chipping cast iron with a steel chisel and steel-faced hammer. He said the blow was a heavy one, and half stunned him; that he was confident he must have been struck with a fragment too large to be buried within the globe. His eye was acutely inflamed; just to one side of the corneal centre there was the scar of a recent wound, which was so plugged with soft lymph as to allow of the aqueous being retained. There was severe iritis, and the pupil was blocked. Atropine freely used during twenty-four hours did not open the pupil. Then, judging that it would be possible, by the aid of an electro-magnet, to ascertain whether or not the foreign body, which from the nature of the circumstances of the accident was necessarily either steel or cast iron, and therefore especially susceptible of magnetic influence, had lodged itself within the globe which it had punctured, I proceeded as follows: Placing the north pole of the electro-magnet before the patient's damaged eye, I completed the galvanic circuit, when he immediately exclaimed that the pain of his eye was unbearably augmented. This clearly indicated not only that the chip was buried within the eye, but that it was materially attracted towards the magnet without. With the patient lying on his back, I held the electro-magnet with its positive pole in close apposition, but not in contact with the wounded cornea, the eyelids being separated by a silver speculum. For some four or five minutes from the commencement of this procedure, the patient complained that the pain was constantly increasing. At the end of ten minutes the iris was seen projecting forward on a sharp point directly behind and in contact with the back of the so recently closed corneal wound. When the magnetic attraction had been further applied for some ten minutes, or for fifteen minutes in all, a metallic surface could be seen penetrating the iris and becoming hidden in the track of the corneal wound. Five minutes later a projecting point was visible on the surface of the cornea, but on withdrawing the magnet to apply mechanical traction to the fragment, it was observed to immediately recede below the corneal surface. The administration of ether was then commenced, as I contemplated reopening the corneal wound, and thus reducing the resistance opposed to the fragment when attracted by the electro-magnet. During the few minutes occupied in the administration of the ether, the application of the magnet was steadily continued, whilst I gave the eye a slight lateral, and up and down, movement beneath the magnet, for the purpose of causing traction upon the chip in alternating directions, and thus loosening it. Simultaneously with the patient coming fully under the anæsthetic influence, this fragment of metal, measuring two by five mm., with sharp ends, passed out of the eye through the track by which it had entered, and fastened itself upon the pole of the magnet. From this time forth the ocular congestion gradually subsided, and he has had no further pain in the eye, which retains good perception of light and normal tension. There is a cataract, also numerous synechia; but he is too well satisfied with the present condition of his eyes to submit to the operative treatment necessary to restore useful vision in the damaged one.

In using magnetic traction upon similar cases, it is important to keep the same pole of the magnet towards the chip; for that is almost of necessity not truly soft iron, and therefore becomes, by induction, itself a permanent magnet, and is consequently attracted by, and attracts with but one of its ends or poles at a time; hence, it was not merely a piece of good fortune which allowed the chip to come out point, rather than broadside, foremost.

It may be better to apply the north, rather than the south, pole of the magnet in the manner just described; as Drs. John Vansant¹ and William A. Hammond,² of New York, have stated that the north pole of a magnet does not cause pain when in contact with the conjunctiva, whereas the south pole, under similar circumstances, occasions a sharp sensation and involuntary twitch; but two or three of you who made the attempt thus to distinguish between the poles of my large electro-magnet failed to detect any difference.

Last Tuesday week, this patient, a bricklayer, aged thirty, of steady habits, whose left eye had been hurt by a chip on the

¹ Journal of Psychological Medicine, New York, April 1879, page 264.

² New York Medical Journal, November, 1880, page 453.

previous day, whilst he was cutting brick-work with a steel chisel and steel-faced hammer, consulted me. The vision was materially impaired, the corneal surface was disturbed at its centre, the lens was unusually visible, and far back, behind the very centre of the lens, a small opacity existed, which returned a metallic lustre when properly demonstrated by focal illumination. The most searching examination, both before and after dilatation of the pupil, failed to detect any further abnormal appearance. When examined through ophthalmoscopic illumination during vertical and lateral movement of the globe, the relative movement of the intraocular opacity, which was unquestionably an iron or steel chip, proved it to be situated in the optic axis, slightly behind the posterior capsule of the lens, through the centre of which it had unquestionably penetrated. During the second twenty-four hours after the receipt of the injury the lens had become slightly cloudy, though still readily permitting a view of the chip. Then was the time for any attempt, if such were to be made, to extract the foreign body, the exact size of which could only be approximately judged from the obliquity of its single visible surface. I will refer presently to the experiments I made to demonstrate by the deflection of a suspended magnetic needle the proximity of the ferruginous chip both before and after magnetizing it by induction. The patient's sensations with the north pole of the electro-magnet, the same as used in the two previous cases, just not touching the cornea, did not enable him to distinguish when the galvanic circuit was completed. The steady application of the magnet produced no visible effect upon the chip other than a questionable change in the amount of metallic reflex returned from it, which suggested that if at all changed in position the chip was lying more obliquely across, but just as far back along the optic axis. I therefore abandoned all hope of extracting the body without the introduction of some instrument into the vitreous, a proceeding not free from risk, but one which I would too willingly undertake with a reasonable prospect of thereby converting a most serious case into a simple one of traumatic cataract. The next question was, with what instrument and in what direction to attempt the extraction of the chip. Having well magnetized the chip by induction, through the proximity of the large electro-magnet, I similarly rendered a sharp lance-pointed cataract needle a permanent magnet, selecting for this purpose a needle likely to be capable of making, during its withdrawal, a passage sufficiently wide for the chip. Introducing the point of this magnetized cataract needle eccentrically through the upper and outer quadrant of the cornea, over the still visible annulus of iris, I carried it through the wide pupil, across the aqueous chamber, to the anterior surface of the lens, through which it passed in a direct line to the chip. After making a little lateral movement with my needle-point against the chip, I gently withdrew the former, to which the latter clung through the whole length of the track along which the needle had been thrust, after it had entered the anterior chamber. Removing the cataract needle from the eye left the chip, which declined to follow through such a minute corneal puncture, lying upon the iris. Making a peripheral corneal puncture with a non-magnetic, bent, broad needle, I passed in the round end of a non-magnetic, cataract, secondary knife, and, withdrawing the same, found the magnetic chip had followed into the corneal puncture, whence it was either washed by the flow of aqueous humor or attracted by the approach of the iris forceps intended to grasp it.

Here is the chip, which weighs (.0012 grm.) twelve ten-thousandths of a gram.

(To be continued.)

— The house staff of Cook County Hospital, Chicago, is to be increased by the addition of six *externes*, to be appointed every six months by competitive examination, and to serve six months. The present staff consists of six *internes*, who serve eighteen months each. The rules adopted for the appointment of the *externes* requires each of these gentlemen to spend at least four hours daily in the service of the hospital.

The number of patients now constantly in the hospital is from 350 to 400, and the demand is for more room. The commissioners are anxious to build an additional pavilion, but the sixty thousand dollars requisite is not forthcoming. A small one-story, independent ward-building is to be built the coming summer for cases of erysipelas and puerperal fever.

CASES OF LEAD POISONING TREATED AT THE MASSACHUSETTS GENERAL HOSPITAL.

BY FRANCIS MINOT, M. D.

My object in reporting the following cases, which have been under treatment, at intervals, since September last, is to call attention to the decided and sometimes rapid effect of the iodide of potassium in relieving the symptoms caused by the introduction of minute quantities of lead into the system during a considerable length of time, as well as to the aid afforded by the internal use of that salt in the detection of lead in the urine. Electricity was also employed in one of these cases for a week, and in another case for several weeks. Both cases were of long duration, but in neither was the electricity continued for sufficient time to have had any probable effect on the disease. The principal symptom in four of the cases is paralysis, which as usual affected chiefly the extensors of the hands, feet, fingers, and toes. The first patient had no paralysis. In one of the cases there was so much atrophy of the muscles of the hands that a diagnosis of wasting palsy was made before a more complete investigation revealed the true nature of the disease. In another the atrophy was less extensive, though well marked. In both these cases the improvement was necessarily slower than in the others, although very satisfactory under the circumstances. A few other considerations suggested by these cases are reserved for the end of the paper.

CASE I.² James C. W., fifty years old, driver of an express wagon, entered the hospital, October 15, 1880. He began to notice a gradual failure of strength and of appetite four months before his entrance; a month later he began to have constant pain over the lower part of the belly, with obstinate constipation, and frequent attacks of nausea and vomiting. The pain was not increased by eating, nor relieved by vomiting. Vomitus consisted chiefly of food, and never contained blood. He was very anæmic and much emaciated. There was no history of exposure to lead. Nothing abnormal was found on physical examination, except some tenderness over the abdomen, which was increased by pressure. No paralysis. No blue line was detected, or could have been detected if present, on account of the foul condition of the teeth. Professor Wood, on analysis, found no lead in the urine. He was ordered a good diet, with opiates and cathartics as required, but no permanent relief to the symptoms followed. Five grains of iodide of potassium were then given three times a day, and at the end of a week a second specimen of urine was examined, which was found to contain lead. The iodide was then increased to ten grains three times a day, and marked improvement of the symptoms followed. At the end of three months the patient left the hospital greatly relieved, though the urine still contained lead. The daily average amount of urine was twenty-six ounces.

He was advised to continue the treatment at home.

CASE II. Lucretia D., thirty-five years old, living in Stoughton, entered the hospital November 4, 1880, with the following history: She noticed that she was

"running down" for three years, but had had no serious illness till two years ago, when she was confined to her bed for seven months. Her symptoms at that time began with nausea, vomiting, constipation, and abdominal pain, which was relieved by pressure. Then followed a gradual paralysis of the upper and lower extremities, till at one time she was only able to move her head. During this period she had several convulsions, with loss of consciousness, foaming at the mouth, and biting of the tongue. At the end of seven months the vomiting and abdominal pain ceased, and she began to gain the use of the hands and feet, the improvement continuing up to the present time; but during the last few months the progress has been so slow that she came to the hospital for advice as to further treatment. She had been in the habit of drinking water which was drawn through a lead pipe. No one in the village was similarly affected, except that two years ago one of her neighbors, who uses the same water, had paralysis of the lower extremities for some months, and then gradually recovered. On her entrance, the most striking sign observed was the "bird-claw" appearance of both hands, with marked wasting of the interossei muscles, strongly suggesting progressive muscular atrophy, though elsewhere the muscular system was well nourished. There was complete paralysis of the extensor muscles of the fingers, and also, to a less degree, of the extensor pollicis. The appearance of the feet much resembled that of the hands, with paralysis of the extensors of the toes, though the atrophy of the interossei was not as marked. She could walk only a few steps alone, and with great difficulty. There was no wrist-drop on entrance, though she stated that there had been previously. No blue line on gums. Bowels constipated. Appetite good. She was ordered ten grains of iodide of potassium three times a day. In a few days the urine was examined, and found to contain lead. After remaining under observation at the hospital for a week, during which time the faradic current was applied to the wasted muscles twice a day, she returned home, with advice to continue the same treatment, and to abstain from drinking water drawn through lead pipes. She returned to the hospital for examination on January 27th, and showed marked improvement in all respects, especially in walking. She came a second time February 21st, when she could walk easily about the room without support, though she did not venture to walk in the street. There was some gain in the extensors of the fingers, but the muscles of the hands were still much wasted.

CASE III. January 3, 1881, Mrs. Mary L., aged twenty-six, was brought to the hospital by her husband from Southbridge, where she has lived for sixteen years, her family consisting of herself and husband, three children, and two boarders. All the water which is used in the house comes through lead pipes from a well near by. Her children, four, six, and ten years old respectively, are in good health; the boarders have been chronic invalids, with indefinite symptoms, for several years. Her husband has been troubled for some time with nausea, vomiting, and abdominal pain, and his gums showed a well-marked blue line. Mrs. L. for the last two years has noticed a gradual but progressive loss of power over the hands and feet, and now she is completely disabled. During the last year she has suffered much from pain in the arms, feet, and abdomen. Bowels constipated, appetite poor. After her entrance she had a convulsion, biting her tongue,

¹ Read before the Boston Society for Medical Improvement, February 28, 1881.

² The cases are reported by Mr. F. M. Sherman, medical house pupil.

but said she had had convulsions more or less frequently since childhood. When seated she could not raise herself, but if lifted to her feet could walk with difficulty, the toes of both feet dropping to the ground. Her arms hung helpless at her sides; there was bilateral wrist-drop, the fingers being tightly flexed, with inability to extend them. Blue line very evident on gums. The urine was diminished in amount, and showed lead in abundance, together with a trace of albumen, the sediment containing a little pus and a few hyaline casts. She was ordered potassio iodide, and at the end of three weeks the record was as follows: "Patient can stand and walk readily, with nothing noticeable as regards gait except weakness. The improvement in the use of the arms is not as marked as in that of the feet. She can raise the right arm almost horizontally; the left arm not quite as much. She can flex the right arm, but not the left. Fingers still flexed, but can be extended a little." She is free from pain, and though the urine still contains lead, she bids fair to make a complete recovery.

CASE IV. Caroline F., single, thirty-five years old, born in Ireland, has been a domestic in a family in Ashburton Place, Boston, during the last four years. The house is supplied, as usual, with Cochituate water, which the patient has been in the habit of drawing from a tank lined with lead, placed in the upper part of the house, for drinking; while the other inmates chiefly used water which came directly from the main, and which did not remain long in the house-pipes; and none of them have exhibited symptoms of lead poisoning. Caroline's health was very good till six months ago, when she began to have a feeling of numbness, accompanied by a sensation as of pins and needles sticking into the left hand, foot, and side. Bowels much constipated. She continued her work till a month ago, when she noticed that she was walking lame. She then went to the out-patient department for a few times; but the paresis of the lower extremities increasing to such an extent that she was unable to walk, she was admitted to the hospital December 28th. Soon after her entrance she was examined by Dr. J. J. Putnam, who reported "that the sensibility of the skin to contact was perfect everywhere, even on the soles of the feet. The tendon reflexes were greater than usual. While there was no loss of power over the upper extremities the gross strength of the lower limbs was decidedly deficient." She could stand alone, but was unable to walk without being supported. In walking the right foot dragged, the toes dropping to the floor. There was no blue line on the gums. Examination of the urine by Professor Wood showed considerable lead, but no albumen and no casts. As in the other cases, the treatment consisted of iodide of potassium and cathartics as required. After four weeks of this treatment she is now nearly ready for discharge. She can walk unsupported, with but little difficulty, and has no pain. The urine still contains a trace of lead, and varies in amount from twenty-five to thirty ounces daily.

CASE V. Mrs. C., "clairvoyante," thirty-three years old, was born in Middle Haddam, Conn. When twenty years old she went to East Hampton, where she was employed during the next three years in casting and polishing coffin trimmings, which were made chiefly from lead. During this period her health was good, with the exception of occasional attacks of abdominal pain, with nausea and vomiting. She never

knew of any one else engaged in this work to be similarly affected. After leaving Hampton she worked in a millinery store for a time, and in 1875 came to Boston, where she has since lived in Green Street. Five years ago, noticing that her hair was turning gray, she began to use "Ayer's Hair Vigor," six bottles of which rendered the hair as black as she desired. This preparation was found, on analysis, to contain a large amount of lead; but the patient is positive that she has used none of it during the last two years. Last August she noticed a feeling of numbness, accompanied by darting pains in the hands and feet; but she continued to do her house-work till one morning in September, when, in attempting to walk from her bed to the window, she felt her ankles "give way," and fell helpless to the floor, where she remained about two hours till assistance came. During this time she was perfectly conscious, but could move neither hand nor foot. On her entrance to the hospital, January 3d, her condition was as follows: "No facial paralysis; protrudes tongue straight, and can move it readily in any direction; pupils normal; partial wrist-drop on both sides; fingers flexed, and inability to extend them; wasting of interossei muscles. She can flex the thighs readily, but cannot move the feet or toes in any direction. No blue line detected; bowels constipated." Analysis of urine gave the following result: "Average daily amount, nineteen ounces; sp. gr. 1027; albumen, trace; sediment contains amorphous urates, pus, vaginal epithelium, and hyaline casts. Much lead present." She was ordered the iodide of potassium and to have the faradic current applied twice a day. Her improvement, though not as rapid as in the other cases, is still marked; and she can now, February 3d, extend her fingers a little and extend or flex her hands readily. She has, as yet, made no decided gain in use of her feet.

The difference shown by individuals in their susceptibility to the poison of lead is seen in Cases II. and III. Out of several families, probably, who drank water drawn from lead pipes, only two persons (Case II.) were affected. In Case III., out of seven members of a family exposed to lead poisoning, two adults showed characteristic symptoms, and two others had indefinite symptoms; while three children escaped entirely.

An interesting fact, which does not seem to have received the attention which it deserves, is that a person may be paralyzed and yet spontaneously recover—at least to some extent—while continuing to drink water containing lead. Thus, Case II. applied for treatment after five years of illness, during the last two of which she showed unmistakable signs of lead poisoning; but for more than a year before her entrance into the hospital there was progressive improvement, and she began to recover the use of her hands and feet, drinking the same water all the time. It is somewhat remarkable that one of her neighbors had a similar experience.

Notwithstanding the frequency with which lead gives rise to chronic renal disease, there is no evidence that the kidneys were structurally affected in any of the above cases; though in two—both of long duration—the urine showed traces of albumen and a few hyaline casts. But the average daily amount of urine was considerably diminished in all the cases in which it was measured. In two of the cases there were epileptic convulsions; but in one of them the patient stated that she had been subject to convulsions from childhood.

THROMBOSIS OF THE MIDDLE CEREBRAL ARTERY.¹

BY OLIVER C. WIGGIN, M. D. HARV.,

Visiting Physician to the Rhode Island Hospital.

SUNDAY evening, June 27th, S. P., a medical student, aged twenty-five, was sitting on the door-steps of a friend, when he was observed to raise his hand suddenly to the left side of his head, and to give a suppressed groan. He immediately rose to his feet and staggered into the house, across a front room into a back room, and threw himself upon a lounge. He was unable to utter a word, but he called attention to his paralyzed right arm and leg by lifting them with the corresponding members of the left side. A few minutes later he vomited, and became restless. I saw him an hour after he fell. I found him tossing his head and body to and fro continuously, at one moment grasping his right wrist in his left hand, at another pulling a pillow over his head and face as if to protect them from the air. There was very marked pallor of the face. He was unable to make a single articulate sound, and he did not appear to comprehend anything said to him. He could not protrude his tongue nor swallow liquids. The entire right side of the body, including the face, was paralyzed. The pupils were moderately dilated; temperature normal; pulse 50, rather full; respiration irregular and sighing; perspiration profuse.

June 28th, nine A. M. Patient remained restless all night. He swallows liquids this morning; temperature normal; pulse 50. He urinates on being lifted to a vessel. Sensation is partially intact in the paralyzed parts. Eight P. M. He protrudes the tongue by request, which turns to the left.

June 29th, nine A. M. He appeared to sleep at intervals during the night; he voided urine twice when requested to do so; he recognized friends. On being requested to move his right hand he picked it up with the left one. When requested to draw up his right leg he worked the toes of his left foot under the right heel and attempted to comply. Temperature normal; pulse 50, and full; takes nourishment well. Eight P. M. He grew worse after noon; he does not comprehend anything said to him; very restless; respiration sighing; temperature normal; pulse 60.

June 30th, nine A. M. He was restless during the night. The breathing grew heavier up to six o'clock, when it became decidedly stertorous; the temperature increased perceptibly about midnight, and is now 101° F.; perspiration has ceased; he has not swallowed anything since last evening; voids his urine unconsciously; pulse 120, weak; flexor muscles contracted; extremities cold; he lies perfectly quiescent; eyes fixed, pupils widely and equally dilated.

He died two hours later, sixty-five hours after the attack.

Previous history. This patient was born cyanotic, but he gradually recovered at the age of four months. After this age he had what his mother described as "large purple spots" on various parts of the body. These spots appeared at irregular intervals up to the age of three years, after which they were not noticed. He was now taken to the West to live, where he had malarial fever in its worst phases. He became pale, weak, and dropsical. Two years later he was so feeble

it was found necessary to return to the East with him. He soon began to recover under the change of climate, and became a bright, active, healthy, and studious boy, entering college at the age of seventeen. From this time onward he pursued his academical and professional studies without interruption. He seldom complained of malaise of any nature whatever. He was, however, of a somewhat taciturn nature. He was a very sound sleeper, and he had the peculiarity of sleeping across the bed with his head hanging over the side. He was subject to attacks of profuse nosebleed. These attacks frequently happened in the night. On several occasions during the six months previous to his death he had several attacks, the real nature of which he would never explain to his relatives. He appeared for a moment to be out of breath, placing his hand over the region of the heart as if in pain. He always recovered in a few moments, if not from the distress, at least his presence of mind, and said it was nothing. These attacks happened two or three times last spring while at the dinner table. He would arise suddenly, clap his hand to his left side, then in a moment resume eating, and turn the conversation from himself. He also had several attacks in the night, which caused him to spring from his bed. These were all that were observed by his friends. On two or three occasions during this period the middle finger of the right hand became numb, and as white as if every drop of blood had been extracted from it. At the same time severe pain shot up the forearm, sometimes reaching to the shoulder. After an hour of rubbing and heating circulation and sensation were restored. He confided to a friend his opinion that these phenomena were due to embolism of one of the arteries of the affected finger. He at the same time predicted that he should die of embolism!

For several weeks previous to this fatal attack, Mr. P. had been hard at work in a machine shop to earn money to meet the expenses of his last course of medical lectures the coming winter. The Sabbath on which he fell and the several previous days were excessively warm and oppressive.

Autopsy, thirty-six hours after death. The subject was of light complexion, medium height, rather spare, but of exceptionally fine and uniform muscular development. Abdominal organs normal; lungs normal; pericardium, normal; heart and large vessels filled with dark fluid blood; chambers of the heart absolutely free from any indication of disease, past or present; but there was no right auriculo-ventricular septum. The two chambers made one continuous conical cavity. The tricuspid valves were laid plaited out closely against the expanded walls, while their lower margins were pulled down smoothly by the tense chordæ tendinæ; but they were nowhere adherent nor in any way diseased. The fossa ovalis was normal. The pulmonary vessels and aorta, together with the other thoracic vessels, were perfectly healthy. The carotids were not examined. The left heart was certainly very muscular, and it seemed to me somewhat hypertrophied, but other physicians present at the autopsy thought its walls no thicker than they should be in a man so muscular and accustomed to vigorous exercise.

The brain. The dura mater was feebly adherent to the left second frontal convolution, evidently the result of very recent inflammation; sinuses free of clots; diffuse extravasation of blood and lymph beneath the sheath of the superior longitudinal sinus, extending

¹ Read before the Rhode Island Medical Society, September 18, 1880.

along two thirds its length, from the torcular forwards; nothing unusual in the appearance of the surface of the brain: a few drops only of serum either in the membranes or ventricles. The middle cerebral artery, with all its branches, was filled with coagulated blood. The clot was confined to those portions of the arteries lying in the fissure of Sylvius. The clot in none of the branches extended beyond the points of entrance into the brain substance. Beyond these points the vessels were empty and collapsed, but nowhere obliterated. The lining of all these arteries was of a bright red color, softened and wrinkled longitudinally. Just within the origin of the middle cerebral, about a quarter of an inch from the junction with the anterior cerebral artery, there was a small area studded with minute granular protuberances. They were five or six in number, of uniform size, about as large as a millet seed. They were subepithelial, and of the same microscopical appearance as the basement membrane (hyperplastic). The epithelial membrane was everywhere intact over these points, and presented no difference in color or texture from the rest of the membrane. The clot was a little firmer at this point, and slightly adherent to the granular surface. At all other points the coagulum rolled easily from the arteries after incision.

On section, nearly all those portions of the brain supplied with blood by these occluded vessels were found in an advanced state of yellow softening. The corpus striatum was completely broken down, forming a mere granular pulp. The softening in other portions, though less advanced, extended outwards to the temporal and second frontal convolutions, involving also the island of Reil. All other portions of the brain were normal.

Comments. Looking at this case without the light of the subsequent autopsy, what would be the most plausible explanation of the phenomena presented? Evidently, one of three things has happened—cerebral hemorrhage, embolism, or thrombosis. Do the symptoms recorded indicate, with any degree of certainty, which of these three lesions has taken place? Frankly, nothing in my own experience, either in private or hospital practice, enabled me to feel certain as to the diagnosis. I find nothing in the age, sex, suddenness of attack, pallor, vomiting, temperature, pulse, unconsciousness, impairment of sensation, extent and location of the paralysis, nor contractions which might not obtain in either of the three lesions mentioned. Nor do I find in the differential diagnosis of authors any great degree of certainty. It is the absence of certain conditions, rather than the symptoms presented in this case, which determined my diagnosis. The chief factor in causation not being perceived, the reasoning led to error. Here was a young man, in apparent health, of excellent habits, and of fine physique, who had never been ill since early childhood, with no perceptible disease of the heart or blood-vessels, with no personal nor family history of rheumatism, scrofula, syphilis, tuberculosis, or carcinoma, with no impoverishment or contamination of the blood. In the absence of these conditions we should hardly expect either embolism or thrombosis. The diagnosis made was cerebral hemorrhage in the region of the left corpus striatum.

The anomalous condition of the heart was not recognized during life. A soft, indistinct, hæmic murmur at the base, attending the systole only, was heard at in-

tervals, but this was not attributed to structural disease. I never examined the patient in health, and I do not know what auscultation would have revealed then. The effect of this state of the heart would be to increase both arterial and venous tension, and to diminish the velocity of the blood current,—two conditions favorable and adequate to the production of thrombosis. My first impression, on viewing the site of the lesion, was that a thrombus had originally formed in the trunk of the middle cerebral artery at the point of the granular protuberances; that shreds had washed from it into the connecting branches, producing emboli, and that the intervening clots were the result of infarction. I think it may be doubted, however, if this theory represents the true order of events. The attack was so sudden and unheralded, and the injury so profound, it seems probable that the entire clot was formed within a period of a few seconds. The clot, moreover, was of uniform color and texture throughout. If the clot was slightly adherent to the granular surface, it was probably due to the mere mechanical advantages of that locality, and not necessarily to an earlier formation. This appears to be a case of autochthonous thrombosis. It is true that the suddenness of the attack is remarkable and, I should say, somewhat exceptional. But there may have been premonitory signs which the reticent patient carefully kept from his friends. The numbness of the fingers referred to in the report, may have been one of them.

The stasis of blood was not due to an enfeebled heart, which, on the contrary, was remarkably vigorous, but to the antagonism of the venous and arterial currents. The point of greatest tension and of least velocity would be somewhere on the arterial side of the capillaries. If there was any element of causation other than the state of circulation, it was probably the depressing effect of the very hot weather at the time of the attack.

It is difficult to account for the granular protuberances, so limited in number and distribution. They were evidently not recent in origin. They were identical in their character and in relation to the arterial structures with those seen in cases of undoubted inflammation of arteries. But why here? I do not regard them as factors of causation of the thrombosis.

The extent, the rapidity, and the character of the softening are of great interest. There was no distinct line of demarcation between the healthy and the diseased brain substance. Nor should we expect any clearly marked area of diseased tissue. The softening would naturally begin first, and be the most complete and rapid in those portions supplied by terminal vessels. As there is no anastomosis here with other vessels, death of the parts is sudden and complete, and the decay partakes of all the characteristics of non-inflammatory softening. The entire mass of the corpus striatum and nearest adjacent parts were of this nature. Their pulpy, granular texture illustrated very perfectly that condition so familiar to pathologists. All this disorganization took place within the brief space of sixty-five hours. The cortical portions of the affected region were in a state much less advanced towards softening. Here collateral circulation very materially delayed decay.

The yellow softening was what would be expected under the circumstances, if the generally received opinion as to the cause of coloring be correct; namely, the staining by disintegrated blood corpuscles en-

trapped in the parts. The occlusion was so extensive, there was no possibility of regurgitation, or setting back of capillary circulation. The arterioles were found collapsed, and hence a large area of brain tissue was anæmic.

The only evidence of inflammatory action in all this wide area of disease was found in a small surface of the pia mater over the left second frontal convolution. The red, softened, and corrugated state of the lining membrane of the occluded vessels, no doubt, took place after the accident.

Aphasia was complete from first to last. Many interesting queries as to the mental state of this patient suggest themselves; but any adequate consideration of them would prolong this report to too great a length.

REPORT ON THE PROGRESS IN MATERIA MEDICA AND PHARMACY.¹

BY W. P. BOLLES, M. D.

THERE has been no important discovery in this line within the past six months, although some interesting investigations are in progress and will perhaps be ready for summarizing in a short time. Several of the newer drugs are being carefully analyzed by eminent workers, but evidence of their medicinal value is more wanting than the details of their composition.

JABORANDI.

In addition to pilocarpine, Messrs. Flarnack and Meyer have obtained a second alkaloid from this drug, which they propose to call jaborina: this alkaloid differs from pilocarpine in its sparing solubility in water and readier solubility in ether. It was separated from commercial pilocarpine, as a colorless amorphous body of strong basic properties, forming amorphous salts. Its action is said to resemble that of atropia upon a frog's heart; no other test appears to have been tried.

QUILLAIA IN EMULSIONS.

Nothing delights an apothecary like the prospect of making an "elegant" emulsion, so we have had emulsions with tragacanth, and other gums, with almonds, egg and pancreatine, in innumerable variations. Now quillaia in tincture appears as an emulsifying agent (it has, we believe, for some years existed in soda water syrups to make them foam). It will "extinguish" mercury, and holds oils, chloroform, copaiba, and resins in fair suspension. From one fourth to one eighth appear to be suitable proportions of the tincture for oils etc. Turpentine and copaiba require an equal quantity of the tincture, and resins still more; of course all with the addition of water.

CHIAN TURPENTINE.

Perhaps this substance received all the attention it deserved in the last report; but as Dr. Clay still maintains that he is justified in his claims for it, and as there is a constant, though moderate, demand for it, coupled with great difficulty in detecting the genuine from the numerous imitations, a word or two more may be accepted.

There are, it seems, only about a thousand old trees

¹ The Pharmaceutical Journal and Transactions. The American Journal of Pharmacy. The Pharmacist. New Remedies. Pharmaceutisches Centralblatt, etc.

in Cyprus, many of them very old and large. For many years little or none of the resin had been collected until last year, when the natives were surprised by the orders from England, and began to gather it again. The quantity from Cyprus can never be large, and collectors are already looking around in Asia Minor and Algeria for larger forests, so far without success being assured.

The description in the last report, although correct for a clean and pure product, does not correspond with the appearance of much of that at present in the market, and believed to be genuine.

Three specimens in the possession of the writer, with a satisfactory history of having come from Cyprus, are briefly as follows:—

(1.) Is a brownish-yellow, not quite transparent, honey-like, very sticky, liquid containing scattered grains of sand and bits of bark. Imported in cans.

(2.) Similar to number one, but darker, thicker, and dirtier.

(3.) Solid, brittle when cold, of a greenish or grayish-brown color, full of impurities (twenty-five per cent.). Imported in lined boxes. After softening with ether and straining the resin is deep yellow.

The odor of all the specimens is characteristic and similar, and the taste free from persistent bitterness.

Two specimens, believed to be factitious, have a coniferous odor, are clean and transparent, without bark, sand, or other obvious impurities, and leave a persistent, disagreeable resinous taste in the mouth. They were probably made from Canada turpentine. The present method of collecting the genuine article is such that a certain amount of bark and dirt is necessarily included, and a perfectly clean product, unless it comes with a history of being strained by reliable hands, should be avoided; but if the demand continues it is to be hoped that a more rational mode of gathering it will yield a more respectable product.

ACONITIA.

Mr. C. R. A. Wright, who has carefully investigated the constituents of the aconites, has given in detail the chemical distinctions between aconitia, pseudaconitia, and "Japaconitia," the two latter the alkaloids of Indian and Japanese species respectively. They are of too nice character for ready pharmaceutical tests, and will fail, therefore, directly to clear up the confusion in which these products have for some time been.

Crystalline aconitia has been for a number of years prepared according to the process of M. Duquesnel, but the alkaloids of the other two species can equally be prepared in crystals.

Dr. Wright considers aconitia to be the chief, if not the only, active ingredient of the roots of *Aconitum napellus*; that it occurs therein with other amorphous alkaloids of lower molecular weight, and containing a higher percentage of carbon. "If the amount of aconitia present relatively to the amorphous bases is not considerable it is often impossible to get it to crystallize at all; in any case a considerable amount of aconitia is retained in solution permanently by the agency of the amorphous alkaloids which thus cause considerable loss." Therefore crystalline aconitia can so far be prepared only at the expense of waste, and remains very costly. Amorphous aconitia, on the other hand, may be good in quality as a small portion of the uncrystallizable bases will suffice to prevent its crystallizing, but there seems to be no good way of determining it unless, pos-

sibly, the physiological one, which at least is inconvenient.

It is to be regretted that we are not in possession of facts showing the physiological differences in quality and intensity of the several alkaloids which are dispensed under the common name of aconitia, since, liable as he is to get any one of several different extremely active substances, without knowing which it may be, or whether it be a mixture of them, the physician cannot but be extremely liable to disappointment or alarm at the uncertainty of his results. It is at present best to prescribe the crystalline alkaloid in small doses, rather than larger doses of the others, which are of uncertain strength.

RESORCIN.

The increasing use of anti-septics in surgery within the last few years has brought to the notice of physicians many compounds, new and old, possessing the property of destroying the different plants concerned in putrefactive changes, and consequently stopping or preventing those processes; and as none of those in use are perfect and free from disadvantages, others will still be offered.

Carbolic acid, the oldest, of course stands first, and is in universal demand. Its disadvantages are its odor, which is offensive to many, its occasionally irritating character, and its serious poisonous effects when absorbed.

Thymol is occasionally used¹ and is very good. Menthol and many others are equally reliable, but no better than thymol.

Dr. Justus Andeer, of Wurtzburg, has just written a pamphlet upon Resorcin, as applied to medicinal uses, and recent numbers of *New Remedies* contain a long abstract of it.

It is a colorless, crystalline substance, of a sweetish and harsh taste, soluble in something more than its own weight of water, also soluble in ether and alcohol. It was first obtained in 1861, by fusing galbanum resin with potash, the result being about six per cent. It has since been made from other resins and in other ways.

Dr. Andeer found that a one per cent. solution prevented the decomposition of urine for months, and also destroyed the organic causes of putrefaction; it preserved pancreas and blood perfectly, retaining even their natural odors. Wounds treated by it healed by first intention, and those poisoned by septic material yielded to it as completely as to carbolic acid. Applied dry to the skin it is not absorbed, and is not irritating; hypodermically a two per cent. solution may produce painful cramps and twitchings, but never abscess. On the moist lips it will raise a white blister. Used with the atomizer it is entirely unirritating to either eyes or lungs, and nearly free from odor. Applied to granulations the crystals are a painless and mild caustic.

Dr. Andeer also recommends its internal use in diphtheria and other diseases, and as injections in leucorrhoea, etc. The dose is one grain to two in water, syrups, glycerine, etc.

— At Bellevue and the University Medical Schools the winter term of lectures closed the 1st of March, but at the College of Physicians and Surgeons the course will be extended until the 1st of May, the spring term having been abolished in this institution.

Hospital Practice and Clinical Memoranda.

JUGLANS NIGRA, A REMEDY FOR DIPHTHERIA.

REPORT OF CASES.

BY C. R. S. CURTIS, M. D.,

Surgeon to St. Mary's Hospital, Quincy, Ill.

IN view of the fact that the mortality from diphtheria throughout our country, and especially in the Eastern States, has been very great for a number of years, notwithstanding the best efforts of the most scientific and successful practitioners, and in the hope that this communication may aid the profession to some extent in their efforts to cure this direful plague, I have been induced to contribute to your journal a short account of the results of some experiments recently made by me with a new remedy (at least a remedy that I have never yet seen recommended in any medical work or pamphlet for diphtheria).

I will premise by saying that in the treatment of this disease I had, previously to July, 1880, adopted about the following plan, with such modifications and changes as the individual peculiarities or the progress of the case might from time to time seem to indicate. Internally quinine and iron in liberal doses, preceded in most cases by a mild mercurial cathartic, also an occasional dose of chlorate of potash, and often, when the symptoms demanded it, I administered an expectorant mixture; the patients at the same time being sustained by milk, beef tea, egg-nog, and other nutritious diet.

Locally, I was in the habit of applying freely over the neck, throat, and parotid glands equal parts of tincture iodine and tincture camphor. The throat was gargled alternately with Ingals' solution of iodine, solution of chlorate of potash, and solution of acetate of lead in dilute acetic acid or with alum in the same, as advised by Trousseau, and the mouth and throat were sprayed frequently with diluted sulphurous acid. This method, I presume, did not differ materially from the general plan of treating diphtheria by many of the best practitioners in this country.

My success was certainly as satisfactory as that in cases generally reported. I could record the recovery of quite a large percentage and number of my cases. Still my treatment did not always succeed, and therefore I felt justified in cautiously trying new remedies where there was a reasonable hope of their proving useful.

About the 1st of last July, while reading Nélaton's *Éléments de Pathologie Chirurgicale*, I came across the following passage in volume i., page 339, in regard to the treatment of pustule maligne. It is to be presumed that the walnut leaves alluded to by Nélaton were those of the *Juglans regia* and not the *Juglans nigra*. But the properties of the various species are said to be much the same. M. Nélaton remarks:—

“En 1853 un praticien de Perpignan, M. Pomagral, annonçait dans les *Annales de Montpellier* qu'il guérissait la pustule maligne par l'application de feuilles ou d'écorce de noyer fraîche. M. Raphaël (de Provins) institua cette médication dans un cas de pustule maligne où il était impossible, à cause du siège et de l'étendue du mal de pratiquer la cautérisation. Le malade guérit. Encouragé par ce succès, le même

moyen fut conseillé dans deux cas où les symptômes ne pouvaient laisser de doute sur la nature de la maladie; le succès ne s'est pas démenti. Voici ce qui se passe sans l'influence de ce topique; l'œdème disparaît très rapidement, les téguments recouverts par les pustules laissent suinter une grande quantité de sérosité, bientôt la pustule s'affaîsse, et la maladie se trouve réduite à une plaie gangréneuse qui s'élimine par l'inflammation des tissus qui la circonserivent, etc.¹

This suggestion made quite an impression on my mind at the time on account of its extreme simplicity, yet as it in reality was not more simple than the discovery of the potency of cinchona bark in the treatment of malarial diseases, and as it was deemed worthy of notice by so distinguished a surgeon as Nélaton, I believed it deserving of serious consideration.

Happening, a short time afterwards, to have a bad case of diphtheria on hand, in a boy about seventeen years of age that was not improving under the usual plan of treatment, it occurred to me that these same leaves of walnut, that had been found beneficial in the treatment of malignant pustule in France, might prove of some service in the treatment of diphtheria, and certainly a trial of them could do no harm. Accordingly, on my next visit, not being supplied with *Juglans regia*, I ordered the parents to obtain a good supply of the leaves of the black walnut (*Juglans nigra*), and to make a strong decoction of them, and use it as a gargle in their son's case, alternating with the other washes and local remedies. This was done. On my visit the next morning I was agreeably surprised to find my patient much improved. The treatment was continued, and at the end of about a week he was well enough to dismiss. How far his recovery was due to the use of the decoction of walnut leaves was a matter of great doubt, and I thought little more about it for some time.

A few weeks afterwards I was called to treat a case of diphtheria a short distance in the country. The patient was a girl about eleven years of age. The symptoms at first were somewhat obscure, as they had been preceded for several weeks by a persistent catarrh. About the second day of my attendance, however, the peculiar diphtheritic membrane became manifest on the tonsils and palate, accompanied by the other symptoms of this most distressing disease. The usual remedies were resorted to until the morning of the third day without any perceptible improvement. The patient, in fact, seeming to be worse from day to day, I then bethought me of my apparent success with the decoction of walnut leaves in the previous case, and ordered the parents to procure and use them in the same manner. I was again agreeably surprised the next day to find my patient better. The treatment was persisted in, and by the end of ten days her convalescence had progressed so far that she no longer required my attendance. During the progress of this case an older sister was taken with diphtheria in its initial form, complaining of pains and difficulty in swallowing, and on examination the peculiar ash-colored deposit was observed on the tonsils. My usual treatment was at once adopted, and in addition the decoction of walnut leaves was ordered to be used freely, and as there was considerable thickening and

œdema of the neck and parotid glands I ordered a poultice to be applied, of the walnut leaves, over the neck and glands. Our success in this case was even more signal than in either of the previous ones, and in a few days she was apparently as well as ever. The ash-colored spots had disappeared. The œdema was gone. The feeling of malaise and all signs of fever had subsided.

One of the greatest difficulties heretofore encountered by physicians in the local treatment of diphtheria has been the painful and distasteful qualities of the local applications. I found, after once trying the decoction of walnut leaves, even when made stronger by the addition of the hulls of the green walnuts, my patients were willing to continue its use, and made no complaint either of the decoction being painful or of its having an especially disagreeable taste, and nurses found little difficulty in swabbing out the throats of young children with it.

After the above related experience I felt more confidence in it as a remedy, and resolved to use it in all my cases. I have now tried it on about thirty patients, gradually depending more and more on the decoction as a local remedy and less on other local applications. I have used it as a gargle, as a poultice, in the form of spray with the steam atomizer, and in children too young to use it as a gargle I have directed the nurses to swab out the throat frequently with the strong decoction. In the worst cases I have added at times portions of the green walnut hulls to the leaves, in order to make the decoction still stronger, with apparently good results; and in one or two instances the remedy has been administered internally with seeming advantage. Since beginning this treatment I have used it in all my cases of diphtheria, amounting to about thirty, and *all have recovered*. I cannot but feel that such satisfactory results must be in a great measure due to the free use of the decoction of walnut leaves. While I do not regard the evidence I am able to furnish as conclusive by any means, I believe it to be so encouraging as to render it my duty to make it known to the profession. In all of the worst cases this treatment has been supplemented by the use of iodine locally, both externally and internally, and by the general tonic course previously mentioned. In the milder cases that I have had to treat recently, especially when called to see the patient early, I have depended on the walnut decoction alone. But whenever a case has seemed severe, or has already considerably advanced, I have also used the iodine locally, a remedy in which I have always had great confidence in the treatment of diphtheria, and which, until the curative powers of the walnut can be more firmly established by a much more extensive experience than I have been able to give it, I could not conscientiously discard.

I believe the experience above related warrants a careful and thorough trial by the profession at large. Many of my cases were bad. In the neighborhood of some of them children were dying of diphtheria under the care and treatment of skillful physicians. In the immediate neighborhood of one of my patients, a girl about ten years old, three children died in one family, and several others near by died, all being treated by good physicians, so that it can hardly be argued that these thirty cases were all favorable, and would have probably recovered under almost any of the usual plans of treatment. Some of the cases, it is true, were mild (at least under the treatment instituted at an early day

¹ The supposed curative qualities of the *Juglans regia* in the treatment of malignant pustule are alluded to in the United States Dispensary (thirteenth and fourteenth edition), but so briefly as scarcely to attract attention.

they never became severe), and the symptoms of malignant diphtheria never developed themselves.

I trust the report above made will be found sufficiently encouraging to induce the profession to give the remedy a cautious but thorough trial, and that my hopes and confidence in it may not be disappointed.

THREE CASES OF DIPHTHERIA TREATED WITH PILOCARPIN.

BY F. W. VOGEL, M. D.

CASE I. Wilbur S., aged six years ten months, taken ill January 22d. The physician who was called pronounced the disease diphtheria and declined to treat on the plea that he had lost three cases the same week. A homeopath took charge for two days, and patient becoming rapidly worse another physician was called, who prescribed chlorate of potash. Patient "becoming choked" I was sent for.

Status præsens: January 25th, 2.30 p. m. Small, ill-ventilated room, patient anæmic, ill-nourished (has always been troubled with a cough). Sits upright in bed; breathing hurried (to 44); eyes staring; constant croupy cough; aphonia; pulse 128, fairly strong; temperature 102.2° F.; retraction of supra-clavicular spaces and of lower ribs during inspiration. Dyspnoea has commenced early last night; ten suffocatory attacks since then. Inspection of fauces reveals nothing beyond a little redness and loaded state of tongue. Father says the doctors saw white patches and that these disappeared after a few swabbings with tincture chloride of iron. Submaxillary glands not tumefied, but subhyoid glands hard and painful. Ordered, according to Guttmann,¹ pilocarp. mur. 0.03, ac. hydrochl. gtt. ii., pepsin sacch. 1.25, aqu. 80.00, S. One teaspoonful every hour, followed by one half teaspoonful of brandy with water, night and day, milk every second hour. A hot compress to the throat every eighth hour. If patient should get worse to double the dose of medicine and wine. Any membranes that might come up to be put into a ten per cent. solution of carbolic acid.

January 26th, nine A. M. Through misunderstanding patient had taken the mixture only every second hour; had had four suffocatory attacks up to midnight, when he coughed up a tubular membrane, forming a complete cast of larynx and trachea down to bifurcation, being over seven centimeters long, very tough and compact at the upper end, where it measured more than one millimeter in thickness, and loose and shreddy in its lower portion. Patient then became quiet and slept in recumbent position during the remainder of the night. He looks a little brighter, voice audible but hoarse, respiration 24, extensive large tracheal râles, pulse 132, temperature 100.5° F., takes nourishment well. Ordered mixture, brandy, and nourishment every hour.

January 26th, six p. m. Passed the day pretty well, had four attacks of orthopnoea, during the last one, about noon, he coughed up a tape-like membrane about three and a half centimeters long and one half wide, which almost choked him, the father pulling it out of his mouth with his finger. Pulse 140, rather weak; no perceptible salivation. Finding the brandy to be largely a diluted with water I ordered a better quality, to continue mixture and brandy every hour.

January 27th, ten A. M. Passed a fair night; three attacks of orthopnoea, during last of which he expectorated another tape-like membrane of the same size as the first one, but looser in texture. Pulse 128, rather small; respiration 24, accompanied by large, loose râles; salivation; he spit out a good deal of muco-pus. Eight p. m. About noon he coughed up another tape-like membrane about five centimeters long, loose and shreddy. Parents were astonished at the ease with which he expectorated it. Pulse 128; temperature 98.4° F.; voice stronger; hoarse; large râles extending over part of back. Takes nourishment quite well.

January 28th, nine A. M. Expectoated with ease another tape-like membrane about four centimeters long, same state otherwise, pulse 120, temperature 99.0° F.

January 29th. No more membranes were brought up, but considerable muco-pus; sleeps now in recumbent position; orthopnoea did not return; pulse 116, stronger; temperature 97° F. To discontinue pilocarpin. One teaspoonful of beef, wine, and iron every third hour; milk or beef-tea and one dessertspoonful of port wine every second hour.

January 30th. No membranes, loud râles, no more orthopnoea, expectorates much muco-pus, pulse 112. Becomes hungry and asks for baked beans; father gives him mashed potato against my wishes.

January 31st. During the night the fire, which had been kept up day and night, went out, it being one of the coldest days of the season. I find the room chilled, patient lying on back, pulse 112, respiration 24, large râles, no change for the worse apparently.

February 1st. I am sent for in haste at seven A. M. Patient has passed a very bad night, orthopnoea, constant restlessness, head bathed in sweat, cyanosis, respiration 42 to 48, pulse rapid, irregular, compressible; wants to be carried and rocked all the time, voice quite strong, hoarse, refuses food and stimulants, tongue dry in centre. Subcrepitant râles over base of both lungs mingled with large moist râles. Mustard to chest. Pilocarpin 0.03; 80.00, one dessertspoonful every hour, one teaspoonful of port wine every half hour. No change at night. Examination of urine shows considerable albumen. Pulse growing feebler. To discontinue pilocarpin and give stimulants every half hour.

February 2d, eight A. M. Very restless night, jactitation, cyanosis has increased, wants to be carried and rocked hard, voice quite strong, pulse not countable, subcrepitant râles over considerable portion of chest. At ten A. M., whilst rocking in his father's lap, he suddenly stretched himself out and expired.

CASE II. Ernest S., aged three years and two months, brother of former, sick for two days, but not taken notice of. In the night from 2d to 3d he became very drowsy, vomited, moaned all night.

February 3d, eight A. M. Drowsy, pulse 144, feeble, face congested, sanious discharge from both nostrils, left nostrils, excoriated. Fauces inflamed, but no exudation, which shows only in the back of the pharynx and tonsils when everted during depression of tongue; there is pain in the left ear, which causes the constant moaning; submaxillary glands enlarged on both sides, especially on right. Put on pilocarpin 0.02; 80, teaspoonful every hour followed by one teaspoonful of port wine; milk, and compress, as in Case I. Eight p. m., exudation has not spread, changed to a dark gray and curls up at edges, tongue very moist but no salivation, pain in ear has subsided, glands very perceptibly reduced in size, pulse 128, takes milk very well.

¹ Berl. Klin. Wochenschrift, 1880, volume 49, page 571.

February 4th. Membranes much detached, submaxillary glands on the left scarcely to be felt, on right very much reduced, pulse 116 strong, sits up and plays. Six p. m. Has become very boisterous in the afternoon, running and climbing about.

February 5th, nine a. m. Is apparently well, fauces still reddened but no swelling or exudation visible, a mucous discharge from the nose continues. To discontinue pilocarpin, spray out nose with lime-water three times a day, and to take sod. sulph. carbol. 0.3 every second hour for the next six days; to continue wine every second hour. Continues well up to present writing.

CASE III. Baby S., aged eight months. Taken ill same day as Ernest, but taken little notice of, until the night from February 2d to 3d, when he begins to have a croupy cough, being very restless.

February 3d, eight a. m. Large tumefaction of submaxillary glands and tonsils, which are partly covered with exudation, pulse about 160; swallowing extremely painful, hoarse cry, little cough, not croupy. Pilocarpin 0.02:80, every hour one teaspoonful, followed by one teaspoonful of port wine. This case was restored to complete health in four days, the pilocarpin producing much salivation.

The membranes in both cases were probably swallowed, since none were expectorated, careful watch being taken.

These three cases add to the testimony of others in regard to the great efficaciousness of pilocarpin in diphtheria. I may add that I have never seen a case of this still much dreaded disease get well as quickly as under this treatment. Even in the first case of laryngo-tracheal diphtheria it did wonders, accomplishing more than tracheotomy could have gained. This remedy ought to be tried in every case, even in full doses of 0.02 to 0.03. Depression of the heart's action was not noticeable, the pulse keeping up as well as can be expected in any case of diphtheria.

New Instruments.

IMPROVED AND NEW POWDER INSUFFLATORS.

BY EDWARD J. FORSTER, M. D.

To those who have given any attention to diseases of the nasal passages, the powder blower of Dr. A. H. Smith, of New York, is well known. Its principle is that of the common wash-bottle of the chemical laboratory, the medicated powder being substituted for water and the force applied by an air bulb.

By practical experience in its use I soon learned that, on account of the convexity of the bottom of the bottle, the powder was blown away from the tube, falling about the sides of the bottle and much of the force of the air being wasted.

Fig. 1, *a*, is drawn to show this:—

To obviate this I had made some stout bottles in shape like a short test tube, the omission of any should-

der permitting them to be easily cleaned if it is desired to change the powder. This, with their size, makes them more convenient to hold in the hand, the concave bottom rendering it unnecessary to keep the bottle on a horizontal plane.

The tubes are made of either hard rubber or glass, the latter being preferable; besides being less expensive, they can be more easily cleaned, powders containing tannin readily blocking the rubber ones.

With some glass tubing, a spirit-lamp, and a slight amount of manual dexterity the tubes can be easily made of any desired length and curve to suit any special case.

To save trouble it is advisable to have a different bottle for each powder in general use. A stand can easily be made by boring the requisite number of holes in a piece of plank.

The long curved tube originally intended for the posterior nares can be readily turned about, as shown by the dotted lines in Fig. 1, *b*, and thus used anteriorly.

In the cut the air bulb is not drawn proportionately large.

By substituting a straight tube for the curved one, the patient can easily be taught to use the blower for the anterior nares, the expense can be lessened by replacing the air bulb with a glass mouth-piece and using the force of the expired breath.

Fig. 2 represents a modification of the Rauchfuss powder blower with the bulb detached. The glass tube has two shoulders or rims at one end, the first of which is inserted into the rubber air bulb; the second prevents the tube from further entering, and the thickness of the bulb lying between the two, is firmly held in place. By crowding the distal end of the tube into the powder a sufficient quantity is taken up.

By this instrument the powder is not well distributed, but deposited in bulk, as it were; and the principal use of this blower is to deposit a powder in one locality, as is the case when sulphur is applied topically to the throat, as many practitioners do about here when treating diphtheria.

Since the cut was made, and the above was written, I have found that if the distal end is drawn out, leaving an opening one half the diameter of the rest of the tube, this insufflator answers fairly well, and has the advantage of being much less expensive than the one made of hard rubber.

For some time I have used such a blower for applying boracic acid to the ear, the tube in this case being only six centimeters in length.

Fig. 3 represents a bent glass tube with an opening in the upper surface of the shorter arm. This I have designated a "spoon" insufflator; for when charging it for use, the opening permits the powder to be easily "spooned" up. This is closed by the tip of a finger, the powder being blown by the breath. This instrument is inexpensive, and answers admirably for the

insufflation of sugar, camphor, etc., for the treatment of "snuffles" in infants, as recommended so warmly by Dr. Robinson in his recent work on nasal catarrh.

These can be made with the shoulders, as the tube in Fig. 2, a bulb added, thus making them available for self-use.

The instruments described can be obtained of Messrs. Leach and Greene, 1 Hamilton Place, Boston.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROUCH, M. D., SECRETARY.

FEBRUARY 28, 1881. DR. T. B. CURTIS presided.

LEAD POISONING.

DR. F. MINOT reported some cases of Lead Poisoning treated in the Massachusetts General Hospital. Vide page 121 of this journal.

DR. ELLIS spoke of the great rapidity of invasion in cases of lead poisoning, one case being reported where it was almost instantaneous. He also remarked on the difficulties which frequently arise in the diagnosis.

DR. WEBBER, in speaking of the detection of the blue line in lead poisoning, said that he had always supposed that where the teeth were not well cared for there was a more favorable condition for the formation of the line. He also spoke of the great variety of symptoms arising from lead, such as tremor, simulating spinal paralysis, and other nervous disorders. Some of these cases which simulate spinal disease are often shown by an examination of the urine to be caused by lead. Dr. Webber also reported a case where the symptoms appeared to be those of syphilis until the diagnosis of lead poisoning was established by the administration of iodide of potash.

DR. JAMES J. PUTNAM remarked that up to the time of these cases of Dr. Minot's he had only found a record of twenty-five cases treated in the Massachusetts General Hospital; he said that there had been a few authentic cases of lead poisoning originating from the use of Cochituate water, and that he was at present investigating the question of how frequently lead is found in this water. Dr. Putnam also spoke of the greater possibility of lead being taken up in the hot-water pipes than in the cold, and of the desirability of keeping the hot and cold water pipes separate in their arrangement.

DR. C. H. WILLIAMS spoke of the immunity noticed among workers in lead in those individuals who drank milk in comparison with those who did not drink it, and suggested that the children spoken of in Dr. Minot's paper might have been protected in this way.

DR. DENNY said that while some authorities, as Charcot, regard the toxic action of lead as essentially peripheral and myopathic, others, as Ranvier, regard it as central, like a poliomyelitis anterior. Another opinion, that it may attack the system peripherally, centrally, or both, even in the same individual, finds support in the following brief abstract of symptoms attributable to lead poison, occurring in cases under my

observation, and principally at the out-patient department for nervous diseases at the City Hospital. In the following four cases the attack appeared to be peripheral in regard to the central nervous system. (1.) Colica pictona and paralysis of extensors of wrists. (2.) Paresis of extensors of wrists. (3.) Constipation, paresis of extensors of wrists. (4.) Extensors of wrists paralyzed.

In the following six cases the effect of the poisoning seemed to be central mostly. (1.) Insanity, complete paralysis, trembling of hands, blindness, nystagmus. Painter. Death. (2.) Apoplexy, aphasia, hemiopia involving temporal half of right and nasal half of left retina. Plumber. (3.) Vertigo, incomplete and intermittent paralysis (saturnine hemiplegia) involving left arm and leg, ambidextral in use of hands. Never had colica pictona. Forty-three years old. Painter twenty-six years. (4.) Saturnine cachexia, anemia, vertigo, constipation, cardialgia. Operative in rubber works. Eighteen years old. Well up to entering factory, five months previously. (5.) Cramps in legs, crural neuritis, anesthesia of thighs anteriorly, no ataxia. Silver watch turned black from lead. Rubber worker. (6.) Paralysis of extensors of wrist, absence of tendon reflex, intermittent aphasia, violent pains (lancinating), beginning in back, heels, and toes, then in legs and arms, ataxia of legs and arms, marked decrease of rapidity in conduction of sensation in legs, exaggerated dyspepsia, complicated progressive locomotor ataxia. Woman, thirty-six. Symptoms began two years ago, after beginning to make, by rubbing with her own hands, a "vegetable preparation" for complexion, containing lead, for sale.

The following cases exhibit evidence of both peripheral and central action. (1.) Painter, twenty-eight. First attack: colica pictona, constipation, trembling of hands. Recovery. Second attack, two years after: constipation, colica pictona, paralysis of extensors of wrist, paresis of legs, trembling of hands. Recovery. Third attack again in two years more: incontinence of urine, paralysis of extensors of wrist, paralysis agitata saturnina, constipation. Recovery, and good health for one year, when, in May, 1880, he began painting again. Fourth attack August 14, 1880: weakness of wrists, vomiting, no constipation or blue line, ataxic movements of hands on attempting special coördinated movements, spills tumbler of water on attempting to drink, cramps in calves of legs, fibrillary contractions of tongue, absence of patella reflex, vertigo, atrophy of inter-osseous muscles of thumbs, paralysis of extensors of left wrist, walks unsteadily. Sent into hospital. September 9, 1880. Patella reflex returned, walks more firmly, improved, handwriting trembling. (2.) Worker for seventeen years in lead works. Thirty-five years old. First symptom, colica pictona one and a half years ago, well up to August, 1880, paralysis of extensors of arms, fore-arms, and wrists, delirious one week.

The occupations were as follows: painters five, rubber workers two, plumber one, brass-finisher one, cosmetic maker one, lead-works operative one, one from drinking lead-water after severe malarial disease. The average age was thirty-four, the youngest was eighteen, and the oldest fifty-one.

The disease is here principally one of the nervous diseases belonging to a handicraft, and its poison, like that of syphilis, or paludal poison, seems capable of setting up disease in the cerebro-spinal as well as in

the ganglionic nervous system. Thus it may cause local trouble in the digestive tract or in the peripheral motor apparatus, while its action seems able to set up degeneration of the cord, either in the posterior column, the anterior column, or in the form of disseminated sclerosis, producing the phenomena of progressive locomotor ataxia, paralysis agitans, senile trembling, apoplexy, delirium, and insanity, in which latter it is marked by hallucinations and a tendency to violent excitement, as seen in the toxic action of alcohol.

Déjerine¹ reports four post mortems where there was paralysis of extensors after lead poison, and found disappearance of axis cylinders and degeneration in muscular nerves and in the anterior roots of the cord, and regards the disease as an affection of the spinal cord.

Friedlander,² in a similar autopsy, found atrophy of extensors and their nerves, extending to the cord, and considers the disease to be myopathic.

More observations are needed to settle the pathology of this disease.

DR. WHITE remarked that the water which has stood over night in the pipes in Boston is liable to show the presence of lead, and that as this had long been known it would be more interesting and instructive to examine the urine for lead of a hundred apparently healthy individuals than the Cochituate water, from which they are supposed to receive the lead, and that until this was done it did not follow that the lead found in the drinking-water necessarily produced the nervous symptoms spoken of.

DR. T. B. CURTIS wished to inquire of Dr. Minot whether, to his knowledge, any one in this country had verified the observations of Potain, Brouardel, and other investigators, showing the existence, in cases of lead-poisoning, of important temporary functional disturbances of the liver. Professor Potain, of Paris, a most trustworthy observer and an admirable clinical teacher, has called attention to the fact that during paroxysms of lead-colic the liver undergoes a remarkable temporary diminution of size, easily recognizable by percussion. Dr. Brouardel, of the Paris hospitals, on the other hand, in the course of his careful investigation of the variations in the elimination of urea and uric acid in hepatic diseases, has found that coincidently with the paroxysms of lead-colic accompanied by retraction of the liver there was a very marked diminution of the amounts of those urinary ingredients eliminated by the kidneys. Thus, in one case, the quantity of urea, which in the intervals of the paroxysms had amounted to twelve or thirteen grams in the urine of twenty-four hours, fell, during the attacks of lead-colic, to three grams. This temporary diminution of the formation of urea which accompanies lead-colic resembles the more marked, less transient, and more deleterious disturbances of the same kind which are known to occur in certain organic diseases of the liver involving a considerable degree of destruction of the hepatic parenchyma, with impairment or arrest of its metabolic functions; such, for instance, as acute yellow atrophy, suppurative hepatitis with large abscess, cancer of the liver, and suppurative angiocholitis due to obstructing biliary calculi. Garrod, to whom, with Charcot, we owe the demonstration of the fact that uric acid is the *materies morbi* of gout, had

already pointed out the important part played by chronic lead-poisoning in the aetiology of gout, especially as affecting the kidneys; and he had shown that, in lead-poisoning, there was a defective elimination of uric acid in the urine and a consequent accumulation of that substance in the blood and tissues. These facts and considerations, with others of similar import, are cited by Charcot, in his recent lectures on the liver and kidneys, as corroborative of the views elaborately expounded by Murchison, according to which the liver is the main seat or headquarters of the metabolic processes by which urea and uric acid are formed, preparatory to their elimination by the kidneys. These views, considered in connection with the analogy existing between certain of the cerebral disturbances occasionally observed in cases of lead-poisoning and the various forms — convulsive, comatose, or delirious — of so-called uramic attacks, have suggested the inquiry whether these disturbances, both in hepatic and in renal diseases, might not be of one and the same nature, though differing in origin. This theory is, however, liable to certain objections, and cannot yet be regarded as proven.

DR. WEBBER reported the case of a man who came to him with the fingers of the right hand tender, swollen, and purple, especially at their ends.

The right side of the face over the malar bone was tender and purple with round hard spots, the right side of the scalp also being affected, somewhat the same appearance was found on the right arm but none on legs or anywhere else. A sphygmographic tracing showed the tension to be much greater on the right than on the left. The affection for which no cause could be assigned was apparently a vaso-motor disturbance leading to a cyanotic condition of the skin.

DR. JAMES J. PUTNAM had also treated the case and spoke of sweating of the fingers being a marked symptom while under his observation.

DR. WHITE, after referring to an observation of Mr. Hutchinson's, made some years ago, that it was not rare to find zoster appearing in patients who were taking arsenic, spoke of a case of double zoster where arsenic had been given which he had reported at the last meeting of the Dermatological Association, and also the case of a gentleman whom he had lately been treating for psoriasis with arsenic, in whom a well-marked zoster developed.

Recent Literature.

A Treatise on the Principles and Practice of Medicine, designed for the Use of Practitioners and Students of Medicine. By AUSTIN FLINT, M. D., etc., etc. Fifth edition, revised and largely rewritten. Philadelphia: Henry C. Lea's Son & Co. 1881.

An extended notice of a book so well and so favorably known as Professor Flint's Practice of Medicine is scarcely necessary, although the progress made in various branches of medicine since the publication of the fourth edition in 1873, and the necessary changes in a work of this character consequent thereon, are very considerable. In making these changes the author declares himself not to have been influenced by any sense of obligation to maintain consistency of views with the previous editions of the treatise, or with other works which he has written. In the light of more recent reflection and enlarged knowledge, some statements made at a prior date seem to him no longer

¹ Virchow's Archiv, Bd. lxxv.

² Progres Med., No. 7, 1879. Déjerine finds destruction of nerve substance in the intra-muscular nerves, nerve trunks, and anterior roots, and believes the disease is probably first central and subsequently peripheral. Soc. de Biologie, February 1, 1879.

tenable; he has, therefore, in this point of view, endeavored to regard his own writings divested of the partiality of authorship, and to subject them to as critical an examination as if they were the writings of another. Dr. William H. Welch, lecturer on pathological histology in the Bellevue College, has contributed in Part I. the first seven chapters, embracing the general pathology of the solid tissues and of the blood; the descriptions of the anatomical characters of the diseases considered in the rest of the volume have also been revised, and in great part rewritten by him. A new section has been introduced devoted to the diseases of the hematopoietic system, the classification of the diseases of the nervous system has been placed on an anatomical instead of a symptomatic basis; and several diseases have been added which were not considered in previous editions.

The summary of recent theories and investigations upon such subjects as tubercle and carcinoma, which are still *sub judice*, though brief and somewhat one-sided, is perhaps as extended as could be expected in a work of this character, or as is desirable in regard to topics still so unsettled. The new part of the book is, in general, very well done. In spite of condensation and omissions the size of the volume is somewhat enlarged, and a half-russia binding gives it a very solid and substantial appearance. In the matter of treatment Professor Flint does not seem to have been affected by recent therapeutical enthusiasms, and those who desire to be assured that so many grains or fractions of a grain of a given drug will drive out so many inches of a given disease must look elsewhere for their authority.

Lectures on Syphilis. Delivered at the Harveian Society, December, 1876. By JAMES R. LANE, F. R. C. S., etc. Second edition. London: J. and A. Churchill, New Burlington St. 1881. Pp. 95.

In 1878 Dr. Lane published three short lectures, showing (1) historically, the progress made in the investigation of venereal diseases; (2) actually, the generally accepted views of the profession at present; and (3) potentially, whither his own views and opinions would tend. The present edition is equally compressed, the three lectures averaging thirty pages in length, while yet the leading features are discussed of duality, contagion in the "secondary" stage, vaccinal, and hereditary syphilis, etc.

Lecture No. 1 traces concisely the principal steps by which progress has been made from the time of Hunter until to-day. Dr. Lane believes with Mr. Hutchinson that "duality is dead," and deals some hard blows to that *deus ex machina* the "mixed chancre." "Syphilization" he justly considers inadmissible as a curative measure, and takes issue with Turenne as to its value as a prophylactic against future contagion. As to "phagedæna," the chief progenitors are regarded as want, neglect, dirt, and drink; no special relationship to syphilis being recognized. A "specific gonorrhæal poison" is denied; clap is an acute urethritis, and may arise subjectively from violent and excessive sexual and alcoholic indulgence, objectively from "whites," menses, etc.

Lecture No. 2 admits the possibility of syphilitic re-infection, and deprecates the hopeless view of the case which is conveyed by the axiom, "Syphilis once, syphilis ever." It affirms that the clinical evidence of the

communicability of an induration at the inoculated point after a period of incubation, and subsequent general affections in due course, by the secretions of "secondary" syphilis, is abundant; that the contagious quality of the blood of syphilitic persons must also now be regarded as an established fact; that it is clearly proved that vaccination with syphilitic blood may convey syphilis, but it is not yet proved that vaccine lymph from a syphilitic child, even though unmixed with blood, will not do so, and it is therefore the height of imprudence to act on any such belief so long as vaccine lymph direct from the calf is obtainable; that as to the physiological secretions of syphilitic persons, the only safe course is to regard every one of them with profound distrust, and to take such precautionary measures and to give such advice as the circumstances seem to call for. The remarks upon "hereditary syphilis" are good, but hardly admit of condensation. Visceral syphilis is barely touched upon.

Lecture No. 3 on "treatment," asserts that syphilis has a strong tendency to get well of itself; that any application of the much abused non-"caustic" nitrate of silver only irritates the sore, and causes inflammation and even phagedæna of the adjacent parts, and that often without even destruction of the sore; that cleanliness, tonics, and mercury are the treatment for early constitutional symptoms, while iodide of potassium has no therapeutic value whatever either in the primary or early "secondary" stage. Dr. Lane is, from personal observation and a five-and-twenty years' experience in Lock Hospitals, an ardent advocate of legislative prevention by means of "contagious disease acts."

An Elementary Treatise on Practical Chemistry and Qualitative Inorganic Analysis. By FRANK CLOWES, D. Sc., Lond. With illustrations. From the third English edition. Philadelphia: Henry C. Lea's Son & Co. 1881.

The present edition of this work, and particularly that section of it which treats of the analysis of simple salts has been carefully revised. The book is eminently a practical one, and we can cordially recommend it as one of the best text-books for practical instruction in the laboratory. The analytical reactions and methods are those which experience has proved to be the most accurate, and the directions for working are given so fully as to be perfectly intelligible to the student without extended verbal explanation from the instructor.

Medical Diagnosis, with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. DaCOSTA, M. D., etc., etc. Illustrated with engravings on wood. Fifth edition, revised. Philadelphia: J. B. Lippincott & Co. 1881.

The first edition of DaCosta's Medical Diagnosis was published in 1864. Since then it has gained a firm place in medical text-book literature, and in the confidence of the general practitioner. A new edition was unquestionably called for; and the present volume will certainly strengthen the reputation and add to the popularity of the book. The chapters on the nervous system and on the blood have been rewritten, and a number of new wood-cuts have been introduced. A German translation is now in process of publication by Hirschwald, in Berlin.

Medical and Surgical Journal.

THURSDAY, MARCH 10, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

A BILL PROVIDING FOR THE EXAMINATION OF RAILROAD EMPLOYEES FOR COLOR-BLINDNESS AND DEFECTS OF VISION.

THE admission on the part of railroad officials of the existence and danger of defective sight as to form and color among those engaged in moving trains, and the repeated advice of state railroad commissioners to have such persons tested in reference to these qualifications, has finally caused the reporting to the Massachusetts legislature, by the railroad committee, of a bill to the effect that—

“No railroad company shall employ any person in a position requiring the distinguishing of form or color signals, unless such person within two years next preceding has been examined for color-blindness and other defective sight by some competent person, and has received a certificate that he is not disqualified, by reason of any defect of vision, to perform the duties of such a position.”

The penalty for this is a fine of one hundred dollars for every such person so employed. The act to take effect July 1, 1881.

This is the third year the attention of our state legislature has been called to the subject. At present, printed documents from abroad, the annual reports of the several departments of the national government and of the state boards of health and railroad commissioners, the published arguments before committees, etc., give us the experience of Europe and this country in deciding the importance and necessity of what railroad officials now admit and railroad commissioners insist on, namely, the physical examination of all employees engaged in moving trains, as to their perception of form and color. Of this need the profession and the community have, however, long been aware, it having been proved to them in many ways. Legislative recognition of this need has at last been secured, and the right of the community to be protected admitted.

The rights of the employee and of the community, however, are not recognized in this bill reported by the railroad committee, in that it fails to protect both, by requiring examinations to be made by those who alone can do so with justice to both parties. The term “some competent person” is a very loose one. Our railroad commissioners have declared any railroad official to be such; the Connecticut commissioners that only experienced ophthalmic surgeons are such, and they could easily prove this by the results in their State. Hence in Massachusetts it will hereafter, under

this act, have to be decided by judge and jury. It certainly would require but a few moments on the part of the counsel prosecuting a railroad corporation to prove the incompetency of any of the laity, and probably of all but a few of the profession, in detecting visual defects. But such incompetency proved on the part of a railroad official who had tested five hundred men on his road would subject the corporation to a penalty of \$50,000 fine.

The laity who are interested, and perhaps even the profession, have till now been rather loath to admit the need of the specialist in these examinations. No doubt this has been largely due to the *seeming* simplicity of the methods employed by those specialists who have brought the subject before the community. History repeats itself, and it may be that we in this country must go through with the experience of Europe instead of profiting by it. There these examinations were first put in the hands of railroad officials, and their reports were simply ridiculous; then the work was transferred to railroad surgeons, and they equally failed till specially instructed by those who had rendered themselves experts by study and by practical experience in testing employees. So that finally, in those countries where the greatest care is taken, the matter is put wholly in the hands of competent ophthalmic surgeons. That this is fairest to the employee, the traveling community, and the stockholder, is self-evident. The last would here be liable to have his pocket touched by the corporation being fined for employing men who possess a certificate from a person proved incompetent to give one. He is also liable to have his dividend “passed” by damages from accidents proved to be due to defective vision, whether from want of eyesight or from color-blindness. Officials admit that the former do occur, and it will not be long before the latter is equally proved, as it has been on the water.

A careful perusal of the printed material above referred to will show that the need of special examiners is as perfectly proved as the need of the examinations themselves, which latter no one, no matter how interested to the contrary, now attempts even to deny. This was certainly very clearly set before our railroad committee. The testimony of medical officers of the government and of some of the railroads, that notwithstanding their experience and study which their duty called for, yet that they were not infrequently puzzled, and forced to apply to the specialist, certainly is most convincing, and we think that this will be the result when any of the profession take up their examinations on the correct carrying out of which so much depends, not only for the examined, but also for the reputation of the examiner. It is to be doubted if any but those very familiar could have, as in Connecticut, so perfectly proved the absurdity of testing for color-blindness by flags and lanterns; and yet all but experts had thought it quite possible, totally ignoring European experience, where this had already been tried and reported on, just as have the Connecticut examining ophthalmic surgeons and the board of health reported. This need of expert examinations is absolutely proved by specialists finding

in Connecticut, among employees already tested by railroad officials informed and instructed by our railroad commissioners, a larger per cent. of color-blindness and defective vision than had ever been claimed as existing even on roads where no examinations were made.

Another most important point is that, by this bill, "any competent person" decides what defect of vision disqualifies for performing the duties of the employee's position. Now the amount of permissible chromatic defect and loss of visual power is not at all decided. The rules advised by the best and highest authority in Europe, resulting from practical experience, were the basis of the Connecticut laws. There is, however, nothing in this bill calling for these or *any* definite standards, either as to methods of testing or requirements. But so important is this that a royal commission in Belgium, in an extended report to the government, urges the forming of an international commission to decide these points for the countries of Europe in general; and as to the navy and marine a bill, as is well known, is now in Congress to initiate a similar international commission for the ocean.

The act which was proposed to the railroad committee caused the Governor and Council to appoint competent medical examiners, who should draw up proper rules, etc., and submit them for approval. Thus all parties interested could be heard, and the examiners would be strictly held by such rules and regulations; they would simply test and report, etc., uninterested in rejection or approval. A bill was also presented the committee providing for an interstate commission, to agree upon what was fairly required of employees engaged in moving trains, in respect to their power of sight and color-sense, and standard methods of testing these by those competent to do so.

Massachusetts now avails herself of the experience of Europe and this country in requiring examinations. Why can she not avail herself of the experience gained as to the equal necessity of such examinations being made only by those who can decide fairly between employee, stockholder, and the millions of people so much of whose lives must be spent on our quickly moving railroad trains? The community await an answer.

REVACCINATION: A REPLY TO G.

"Now, here's another discontented paper," as Shakespeare has it, yet another complaining and capacious correspondent, expostulating in unmeasured terms against our recent editorial on small-pox and revaccination, and charging us with various unpardonable offenses, both of commission and of omission. We are somewhat surprised, we must confess, by the *manner* as well as by the matter of the protests which have been entered against our statements, and we are quite at a loss to account for the markedly polemical animus so freely displayed by our correspondents in their attacks. We will, however, once more attempt to meet the objections and criticisms — such, at least, as admit of comprehension and discussion — again in-

curred by our remarks on the prophylaxis of small-pox, after which we trust that our readers will be spared the further continuance of a controversy so profitless, to say the least, as that which has been forced upon us.

Taking up successively, one by one, the questions raised by our correspondent, we must, in the first place, vindicate our entire right to address our readers on the subject treated of in the indiscriminated article, and maintain the absolute propriety and opportuneness of our remarks and admonitions. G., referring to "those who have authority to speak on the subject," adds that he alludes "of course to our board of health." In thus implicitly restricting to our sanitary board the authority to speak on the prophylaxis of small-pox, and denying our own competence and right to an independent voice and action in the matter, our correspondent shows that he is manifestly confounding two distinct branches of sanitation, the duties and responsibilities of which lie in wholly opposite directions. *Public hygiene*, to be sure, comprising, as agencies designed to prevent the spread of small-pox, isolation and *compulsory* vaccination, concerns our sanitary authorities. This province we did not venture in the remotest manner to infringe upon, though, in our editorial capacity, we should not feel called upon to refrain from suggestions or criticisms, should such outside intervention in the affairs of our sanitary government seem at any time called for. The domain of *private* or *individual hygiene*, on the other hand, belongs wholly and exclusively to the physician and to his patient; and in times like the present, of foreboded prevalence of small-pox, it is not only the right but the bounden duty of the physician to see to it that his patients receive *in due season* the benefits of the requisite precautions against the disease. This is a matter of private hygiene, lying between the physician and his patient, which does not in the least concern the sanitary authorities, in which they very properly forbear to interfere, and in which any attempt at intervention on their part would only be an unwarranted intrusion.

No one more fully recognizes than ourselves the admirable efficiency and the entire competence of our municipal sanitary board; but we are not in the least disposed, for aught G. or any one else may say, to abdicate the right of dealing, in these editorial columns, with any such questions of private or even of public sanitation as may seem to us expedient, whether in the interest of the profession, or of the public, or of both. Boards of health, though active, are mostly silent bodies; *acta, non verba* is their motto; it is not their province nor their habit to undertake to teach the medical profession its duties; nor do we, as physicians, look to them for instruction or guidance in matters which are manifestly of our own special and technical competence. On the other hand, it is not only the right but the plain duty of a medical journal to do all in its power to raise, agitate, and discuss questions of interest to the profession, and to dispense information and advice bearing upon all medical subjects, whether relating to the theory and practice of medi-

cine and surgery, or, as in the present instance, to sanitation, public or private.

The object of our article, then, was simply to warn our readers of the possible and *probable* advent of small-pox, in order that the resources of private hygiene might be voluntarily brought to bear at once, in order that vaccination might be attended to *in season*, without the homicidal delays shown to have occurred at the time of the last great epidemic of 1872-73. It did not in the slightest degree enter into our intentions or our programme to touch upon the duties of the board of health, of which our correspondent has so gratuitously constituted himself the hot defender and expounder. These same considerations suffice to show the inanity of his blundering charge that our "omission of even a reference to the very thorough work in the way of vaccination and re-vaccination in this city in 1872-73 is inexcusable," etc.

Alluding to our editorial article, G. says that its "*only result* (excepting, of course, the general public excitement and the consequent rush for vaccine matter) has been the article by Deltoid," etc. Now this altogether disinterested testimony to the *complete success* of our undertaking is in the highest degree gratifying to us, especially when we take into account the quarter from which it comes, and the shape in which it is conveyed. Deltoid's communication, to say the truth, we have not looked upon as a particularly valuable fruit of the agitation which we thought it expedient to arouse; though G. seems disposed to rate that rather intemperate epistle, those "wild and whirling words," as on the whole the most important result of our efforts. But the "general public excitement" and the "rush for vaccine virus," alluded to in an accessory and disparaging way by our correspondent as our "only" achievement, happened to be exactly what we wanted in the way of "results," and absolutely *all that we wanted*. What other ends G. can have supposed us to have had in view we are wholly at a loss to imagine, and leave to the ingenuity of our readers to find out.

G., referring to our very temperate appeal in favor of the usual measures of prophylaxis against small-pox, says that he "will not stop to investigate whether the existing state of affairs in Boston and the surrounding country is such as to warrant such a note of alarm, . . . as that is a matter on which argument is impossible." He nevertheless, although having thus explicitly acknowledged his inability to justify his conclusion by any evidence or process of reasoning whatsoever, does not hesitate to assert, further on, that it seems to him "that there is no occasion for alarming the public," and that he does not believe it advisable under the present circumstances to start "a popular scare."

Being thus challenged to justify what G. calls our "note of alarm," or, as we would rather say, the *warning*, which, upon due consideration of the past and present state of affairs here and elsewhere, we felt called upon to convey to our readers; and not finding ourselves at all disposed to agree with him in

looking upon this topic as "a matter on which argument is impossible;" being, on the contrary, of the opinion that herein is the fundamental question wherein we find ourselves absolutely at variance with G., as well as with Deltoid, both of whom deprecate what they choose to call a "panic" or a "popular scare" as unnecessary or premature, we will simply call attention to the following *facts*:—

For nearly a half century small-pox has been almost constantly present in Boston, the only years in which no deaths by this disease were recorded being 1833, 1844, 1878, and 1879. In that space of time we have undergone at least six distinct epidemic recrudescences of variola, each of which has generally lasted between one and two years, and has been followed by an interval of six or seven years, during which a few yearly deaths have occurred, due to imported or sporadic cases. Ever since the introduction of vaccination at the beginning of the century, the severity of these successive epidemics has been growing greater, culminating in the last, which subsided in 1873, after a duration of about a year. The following figures, exhibiting the yearly death-rates by small-pox per 100,000 living, in Massachusetts, during twenty-four years, from 1851 to 1874, shows the increasing severity of the disease:—

Years.	Death-Rates.	Years.	Death-Rates.	Years.	Death-Rates.
1851	12	1859	21	1867	15
1852	3	1860	27	1868	2
1853	4	1861	3	1869	4
1854	19	1862	3	1870	9
1855	29	1863	3	1871	19
1856	12	1864	19	1872	67
1857	2	1865	17	1873	43
1858	1	1866	11	1874	2

The American epidemic of 1872-73 followed closely upon the great transatlantic epidemic of 1871-72, which raged in Great Britain and all over the continent of Europe during the Franco-German war, following the footsteps of the contending armies in the field and harassing the troops within and around the beleaguered cities. The epidemic of 1872-73 proved fatal to 1040 persons in Boston, of whom nearly 70 per cent. were adults, aged 15 years and over. In Suffolk County, in the year 1872, when the epidemic was at its height, the deaths by small-pox amounted to 73.27 per cent. of all the deaths so caused in the State of Massachusetts, although the population of the county did not exceed 22 per cent. of that of the State.

Now, this great epidemic lasted everywhere about a year. In pretty much all localities, *whether provided or not with boards of health*, it subsided spontaneously at the end of about a twelvemonth, when the previously accumulated stock of predisposed subjects had become exhausted; the fire then died out for want of fuel; the combat ceased for want of combatants. It is therefore extremely doubtful, to say the least, whether the sanitary authorities of any of our cities really deserve to be credited with the "stamping-out of the epidemic of that period," so un-

hesitatingly affirmed by our correspondent G. If he had wanted to do full credit to the unquestioned efficiency of our municipal Board of Health, he ought to have enlarged upon the more recent and very severe epidemic of 1875-76 which in those two years killed 1651 persons in Cincinnati, and in the year 1875 caused 1280 deaths in New York, and which we entirely escaped in Boston (four deaths only taking place), thanks, without doubt, to the vigilance with which the flying sparks were stamped out by our sanitary guardians as fast as they fell within the limits of our community, as well as to the other precautions initiated in the course of the epidemic of 1872-73, and carefully maintained ever since by our Board of Health.

Such having been our experience of small-pox in the past it now behooves us not to be unduly sanguine with regard to the future, but to act at once upon the probability of the disease being at hand. To be sure, we *may* escape it altogether, as was the case in 1875, though it is in the highest degree unlikely that we shall continue indefinitely to enjoy such immunity. Small-pox may not appear for six months or more; but, on the other hand, it *may be established in our midst to-morrow*; and nothing could be more unwise, more criminally imprudent, than to allow ourselves again to be overtaken by it, unprepared, as in 1872. Therefore let us at once, without alarm or panic,—such excitement being wholly superfluous and uncalled for,—hasten to make up our arrears of prophylaxis, by vaccinating, as speedily as possible, all unvaccinated infants and children, even if under the age of legal requirements, and by revaccinating all adults whose primary vaccination is such as to afford insufficient guarantees of protection.

Such was our advice to our readers. The propriety and opportuneness of our warning is corroborated by the recent circular of our State Board of Health, setting forth the existing legislation with regard to vaccination and small-pox, in which it was stated that "the State Board of Health, Lunacy, and Charity voted at its regular monthly meeting, February 5th, that a communication be sent to the towns of the Commonwealth urging the importance of a protection of the people before small-pox appears in this State," and urging that, "in view, then, of the possible appearance of small-pox in this State, it is earnestly desired that a vaccination of all unprotected individuals should be made," etc.

Another circumstance, which testifies strongly to the opportuneness of the recent and present extensive resort to revaccination in this community,—the latter having been largely consequent upon our appeal, and presumably a result of it,—is the unusual susceptibility to vaccinia now being displayed by revaccinated adults. In ordinary times, revaccinations are apt to be unsuccessful in a large majority of cases; but, as Prof. W. B. Davis, of Cincinnati, says in a very instructive paper on Revaccination, published in the *Journal* a few years ago, "exposure to infection and to intense epidemic influence largely increases the susceptibility of the system to the influence of vaccine

virus, and accounts for the unusual number of successful revaccinations during the existence of an epidemic."

Finally, in further justification of the so-called "scare" with which, to our great gratification, we are credited by our critics, we will appeal to the general assent and compliance with our advice so promptly exhibited by the profession of the city and its environs, and made manifest by the "rush for vaccine matter," admitted by G. to have followed as one of the results of our article.

Several points, incidentally and lightly touched upon by our correspondent, still call for comment. He ventures upon the entirely gratuitous and absurd insinuation that we are actually so fatuous as to suppose that "the idea of the necessity of revaccination is a new one." Now we must say that we are utterly at a loss to imagine by what perverse exercise of misdirected ingenuity he can have fancied that any portion of our remarks could be twisted into any such appearance of pretention on our part. His misconstruction of our statements with regard to this comparatively unimportant point can hardly be accounted for, save by a hasty and prejudiced perusal of our article. We are so confident that he stands alone in this singular interpretation that we will not risk importuning our readers with any discussion of the point. We will only advise our correspondent to reread attentively what we have said; and if, on careful re-perusal, he still clings to his disparaging view, we shall simply have to do our best to resign ourselves cheerfully to his very unfavorable estimate of our intelligence and modesty.

G. accuses us of "ingeniously twisting" Marston's (not Marston's) statistics of comparative mortality by small-pox among different categories of patients (unvaccinated, ill or well vaccinated, and having previously had small-pox), with the object of bearing out our own statement, as well as that quoted from the *Lancet*, to the effect that the protection afforded by vaccination, and *a fortiori* by revaccination, was greater than that accruing from antecedent small-pox. We are really gratified by this recognition of our ingenuity; we accept the unexpected compliment with all the modesty at our command, and only regret that we cannot return it. G. says of Marston's table of figures that "it does not, of course, prove anything of the sort, but simply shows that in cases where the disease attacks a person a second time the ratio of mortality is high." He here concedes all that we wished to establish. We have almost always found that the chief preoccupation and most earnest wish of sick people was to survive. When small-pox, or any other disease, has proved fatal, we have been in the habit of looking upon the means of prophylaxis employed as defective; the deficiency of protection being, in our eyes, proportional to the degree of mortality. Of course, post-variolous small-pox is met with very much more rarely than the post-vaccinal disease, inasmuch as there is an infinitely greater supply of vaccinated individuals about than of persons offering the necessary conditions for second small-pox; namely, having never

been vaccinated, and having already experienced and survived small-pox. Our statements touching the superior protection afforded by vaccination are corroborated in the paper by Professor Davis, already quoted from, one of the conclusions of which, based upon cases observed in Cincinnati during the very severe epidemic of 1875, was to the effect that "variola and varioloid give no more protection from a recurrence of variola than vaccination."

With regard, finally, to the charge of presumption, finely implied in our correspondent's last "homely" paragraph, we hardly know what notice to take of it. Our space, and probably the patience of our readers, are alike exhausted, and we will only observe, for the sole benefit of G. himself, that we are making it our particular business, in these editorial columns, to give instruction of the kind alluded to by him, — to which he will himself always be welcome, — and that we propose in future, without allowing ourselves to be at all discouraged by this gratuitous protest against our competence, to continue our best efforts in behalf of the dissemination of such information as it is the legitimate province of a medical journal to impart to its readers.

BELLEVUE HOSPITAL MEDICAL COLLEGE: A DISHEARTENED REFORMER.

In the issue of the *JOURNAL* for January 27th extracts were made from the annual report of Harvard University for 1879-80 relating to the medical department of the university. Tables were reproduced, giving statistical information concerning the working of preliminary examinations and extended time requirements for a degree.

In conclusion we sympathized with the regret expressed by the president of the university that similar statistics are not published by other prominent medical schools, and expressed the hope that they might be stimulated to an honorable rivalry accompanied by such a "fair count" as might make the figures really valuable for comparison. The nearest approach to a response to the expression of this hope, which we have as yet noticed, is a somewhat euphemistic circular issued by the faculty of Bellevue Hospital Medical College, the greater part of which we reprint, even at the risk of increasing the usefulness of so prudent an institution.

The faculty of the Bellevue Hospital Medical College introduced, for the session of 1880-81, important changes in the curriculum of instruction and in the requirements for graduation. The preliminary term was abolished, and the regular winter session was extended to six months. Attendance upon three winter sessions was made obligatory. Students were required during the two first years to attend all the lectures, didactic and clinical, and at the end of the first and second years to pass examinations in chemistry, anatomy, physiology, materia medica, and therapeutics. An examination in these branches having been passed, the third year was to be devoted to the practical departments of medicine, surgery, and obstetrics. The requirements embraced, in addition to dissections, practical courses in chemistry and histology. Provisions were also made for additional exercises in the three practical departments. These exercises, consisting of personal examinations in cases of disease, the performance of surgical operations on the cadaver, and demonstrations in gynecology, were limited to third-course students. These changes were made by the faculty with entire unanimity

and with the expectation that a considerable pecuniary sacrifice would be demanded on the part of its members, who were actuated solely by a desire to secure a higher grade of professional acquirements for the graduates of the college.

The experience of the session of 1880-81 has led the faculty reluctantly to the conclusion that to persist in the requirement of attendance during three courses will be to incur a risk as regards the interests of the college, which they do not feel justified in assuming; and the purpose of this announcement is to state that, after the present session of 1880-81, attendance during a third session will be optional and not obligatory. This college, like most American medical colleges, is self sustaining; and the special provisions for instruction which have been and will continue to be maintained call for a large expenditure of money as well as of time and labor. With an undiminished desire to continue the requirement of three sessions, and with not less willingness than heretofore to make whatever personal sacrifices may be necessary, the faculty feel obliged, by a proper regard for the prosperity and usefulness of the college, to return to the requirements for graduation which were in force prior to the session of 1880-81. In making the changes introduced during this session, it was foreseen that a large proportion of the students in this college coming from distant parts of the United States, the necessary expenses of spending three winters in the city of New York would render difficult or impossible the attendance of many who would otherwise join the classes. Many students, of course, would be led to attend other colleges which require only two sessions for graduation. It was hoped, however, that the progressive movement of the Bellevue Hospital Medical College would secure approval and coöperation on the part of the medical profession sufficient to render the change feasible. In so far as a judgment can be formed from the present session the profession is not prepared to sustain the movement.

In announcing a return to their original requirements for graduation, the faculty desire to state that all the new additions to the curriculum will be retained. It is not proposed to recede in the least from these. Students will have the same opportunities for practical exercise in the different departments as those enjoyed by the class of 1880-81. For those who choose to attend during three sessions, the provisions as respects examinations in the elementary branches at the end of the second year, and an exclusive devotion to the practical departments during the third year, will be continued. To all students who are able to do so, now, as hitherto, attendance during three years is strongly recommended; and, from the number of those who have already matriculated with the expectation of attending three sessions, the faculty entertain a belief that not an inconsiderable proportion of future classes will voluntarily follow their example.

Notice is herewith given that, for the session of 1881-82, the requirements for graduation will be three years' pupillage, after eighteen years of age, and attendance upon two full courses of lectures, the last being at the Bellevue Hospital Medical College.

February, 1881.

After one session of well-doing the Faculty of the Bellevue Medical College has lost heart. Having put its hands to the plow, it turns back before the dew is fairly off the grass, not so much because it dislikes the sun as out of regard to the plow.

A judgment formed upon so short an experience might safely be termed a "snap" judgment, but if its judgment is correct the Faculty seem willing to consider its own lack of perseverance as attributable to a want of approval and coöperation on the part of the medical profession!

It is very important that this country should possess medical schools with high standards, whose degrees mean something positive, but we cannot see that it is otherwise of any inherent consequence, unless possibly to the members of its Faculty themselves, that any particular medical school should continue to exist.

We congratulate our excellent contemporary, the *New York Medical Record*, upon its manly and straightforward editorial remarks on the Harvard Medical School and Reforms in Medical Education, in its num-

ber for February 26th, from which we make the following extract:—

"The Harvard school is one of the few medical institutions which dares to publish the figures showing the number of students who come up for final examination and the per cent. rejected. The proportion last year was nearly one third. It is the belief that in one of the largest, if not the largest, college in this city the proportion rejected is about one fiftieth!—which means that all but a scant half dozen are rushed through the tests, to the great financial comfort of the college and the shame and damage of the profession.

"With the manifest benefits which a system of medical education like that of Harvard confers upon our profession, it is a duty, as well as for its interest, to encourage this particular school and all others conducted on a similar plan."

It is very desirable that a school should have the encouragement of the profession in its efforts at reform in medical education, but encouragement here as in other matters is most apt to be shown to those who manifest a strong tendency to help themselves.

MEDICAL NOTES.

—Professor Bigelow's operation of litholapaxy has at last successfully invaded both Vienna and Paris, and is meeting with the appreciative recognition previously bestowed on it elsewhere. Professor Billroth (*Wien med. Wochenschrift*, Nos. 44 and 45, 1880) and Professor Dittel (*Allg. Wien. med. Zeit.*, No. 44) recently referred to the operation in terms of generous approbation. M. Rousseau, of Paris, in the last number of the *Archives Générales*, speaks of litholapaxy in terms of unqualified praise.

NEW YORK.

—Dr. T. Gaillard Thomas's beautiful new private hospital for the treatment of diseases peculiar to women, at the corner of Lexington Avenue and Fifty-Second Street, has now been opened, and any patient admitted there will be sure to have every possible provision made for her comfort as well as to receive such treatment as the highest skill and science can suggest. The resident surgeon is Dr. James B. Hunter, of the attending staff of the State Woman's Hospital, and his own private office is located in the building.

Miscellaneous.

RESECTION OF THE STOMACH.

MR. EDITOR.—It is well known that resection of the stomach has, up to the present time, never been successful; but it gives me much pleasure to state that the operation has at last been performed with the most satisfactory results. On January 29th, Professor Billroth, in an operation which I had the advantage of witnessing, removed the pylorus and about one third of

the stomach for carcinoma, and the patient has made a good recovery.

In his public clinical lecture on the 31st, Professor Billroth gave an account of the case, as well as a short history of the operation and the experiments that have led to its successful performance. The substance of this lecture appears in the *Wiener Medizinische Wochenschrift* of February 5th.

The history of the operation is as follows: In 1810 Merrem published a work on this subject, giving the results of his experiments on dogs, two out of three having survived the extirpation of the pylorus and sewing together of stomach and duodenum. In spite of these results, the operation was not attempted on man, and, though surgeons of different nationalities investigated the subject, no material advance was made until Lambert discovered the true method of uniting all wounds of the intestinal tract: namely, apposing the serous surfaces. After this, recovery after sewing up of intestinal wounds became more frequent.

In 1871 Billroth excised a part of the œsophagus in a large dog, the operation being followed by recovery. Czerny first performed this operation on man with good result. This was shortly followed by the experiments of Gussenbauer, Winiwarter, Czerny, and Kaiser on resection of different portions of the intestinal tract in dogs. These operations, when performed with antiseptic precautions, were very successful, and in one case the whole stomach was removed, and the œsophagus and duodenum united with good result.

In 1877 Billroth operated on a gastric fistula following abscess by opening the abdomen at that point, excising the thickened, adherent edges of the gastric opening, sewing up the wound, and returning the stomach to the abdominal cavity. The patient made a good recovery.

In 1879 Péan, of Paris, first resected the pylorus for carcinoma in a patient who was greatly exhausted by the disease, and who died on the fourth day. Catgut sutures were used.

The present case is that of a woman, forty-three years of age, who had had the usual symptoms pointing to cancer of the stomach for more than a year. The patient was very anæmic and weak, having been able to retain only very small quantities of sour milk for several weeks. A freely-movable tumor could be felt in the epigastrium through the thin, flaccid abdominal wall lying slightly to the right of the median line.

The operation was performed in the small room always used for large abdominal operations, the temperature being high and the air moist. The stomach was washed out and a nearly horizontal incision, eight centimeters long, was made over the tumor, which was drawn out through the opening. It was found to involve the pylorus and about one third of the stomach.

First the greater and then the lesser omentum were ligatured and cut through close to the tumor, and the whole stomach being drawn out of the abdominal cavity, was divided, the cut beginning at the lesser curvature and passing about half way through the stomach, one centimeter from the infiltrated portion. The duodenum was incised in like manner, and six trial sutures were passed through the cut surfaces, but not tied. It being found that the edges could be easily brought together, the incisions were continued through both stomach and duodenum, and the tumor thus wholly removed.

The oblique wound in the stomach was then sewed up, beginning at the greater curvature, until an opening was left which corresponded in size with the duodenum, which was then stitched into the opening. Lambert's stitch was used throughout, fifty-four carbolized silk sutures being applied.

The stomach was then washed with two per cent. carbolic solution, and the whole returned into the abdominal cavity, which was closed in the usual manner. A carbolized gauze dressing was applied, which was not removed until the sixth day. The spray was not used. Hemorrhage throughout the whole operation was very slight, and no blood or fluid from the stomach was allowed to get into the abdominal cavity, warm carbolized compresses being packed behind the stomach while it was open.

The mass removed measured on the greater curvature fourteen centimeters; the pyloric opening allowed only a large probe to pass.

Since the operation there have been no unfavorable symptoms; no fever, no vomiting, scarcely any pain; in fact, the patient has been much more comfortable than for weeks before the operation. The external wound has entirely healed.

Wine and peptone enemata were given for two days,

and since then only wine. By the mouth, only ice for the first twenty-four hours, then milk in small quantities. On the eighth day *bouillon*, with egg, and later meat and apple *purées* have been taken without bad effect.

Now, on the fourteenth day, the patient is allowed to sit up, and in a day or two will be able to take meat and other solid food.

The success of this operation marks a great advance in abdominal surgery, and enlarges still farther the field of the surgeon. The technical difficulties of the operation are not greater than in many other cases; even the difficulties of diagnosis are now much lessened when the abdominal cavity can be opened and its contents examined with almost no danger to life, and the methods of illuminating and exploring the interior of the stomach are being daily more and more perfected.

The operation may not always be successful or applicable to all cases, but it will relieve, even if it does not permanently cure, many patients whose sufferings are generally intense, and who have absolutely no hope of cure by the means hitherto employed.

SAMUEL J. MIXTER, M. D.

Deaths reported 2913; 1096 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fe-

vers) 620, lung diseases 476, consumption 407, diphtheria and croup 209, scarlet fever 112, small-pox 65, typhoid fever 43, malarial fevers 40, diarrhoeal diseases 34, erysipelas 31, cerebro-

spinal meningitis 28, measles 27, whooping-cough 20, puerperal fever 10, typhus fever one. From *typhoid fever*, Philadelphia eight, Chicago seven, Boston six, New York and St. Louis three, Providence and Lawrence two, Brooklyn, Baltimore, Cincinnati, New Orleans, District of Columbia, Pittsburgh, Charleston, Lowell, Holyoke, Chelsea, Attleborough, and Weymouth one. From *malarial fevers*, New York and St. Louis 11, New Orleans and District of Columbia five, Chicago, Baltimore, Cincinnati, Buffalo, New Haven, Lawrence, Chicago, and North Adams one. From *diarrheal diseases*, New York seven, Chicago and New Orleans four, Philadelphia three, Brooklyn, St. Louis, and Providence two, Boston, Baltimore, Cincinnati, Buffalo, Milwaukee, Lowell, Lawrence, Attleborough, Spencer, and Amherst one. From *erysipelas*, New York and Chicago six, Philadelphia and St. Louis four, Brooklyn three, Boston and Cincinnati two, Buffalo, Milwaukee, Providence, and Salem one. From *cerebro-spinal meningitis*, New York seven, Chicago four, New Orleans three, Philadelphia, Baltimore, Lynn, and Holyoke two, Boston, St. Louis, Cincinnati, Milwaukee, Worcester, and Newburyport one. From *measles*, New York six, Boston and Nashville five, New Orleans three, St. Louis and District of Columbia two, Milwaukee, Providence, Lowell, and Fall River one. From *whooping-cough*, New York four, Brooklyn, Chicago, and Baltimore three, Boston two, Philadelphia, St. Louis, Buffalo, Nashville, and Milford one. From *puerperal fever*, Chicago and St. Louis three, Brooklyn, Cincinnati, Lowell, and Fall River one. From *typhus fever*, New York one.

Twelve cases of small-pox were reported in Brooklyn; 30 in Chicago; one in St. Louis; seven in Pittsburgh; diphtheria

42, scarlet fever two, in Boston; scarlet fever 16, diphtheria eight, in Milwaukee.

In 43 cities and towns of Massachusetts, with a population of 1,114,439 (population of the State 1,783,086), the total death-rate for the week was 22.79, against 22.17 and 20.97 for the previous two weeks.

For the week ending February 5th, in 149 German cities and towns, with an estimated population of 7,838,433, the death-rate was 27.4. Deaths reported 4127; 1772 under five: pulmonary consumption 606, acute diseases of the respiratory organs 485, diphtheria and croup 165, scarlet fever 76, typhoid fever 63, measles and röteln 58, whooping-cough 50, puerperal fever 25, small-pox (Königsberg two, Munich) three, typhus fever (Posen) one. The death-rates ranged from 14 in Hanover to 36.4 in Nuremberg; Königsberg 29.5; Breslau 29.8; Munich 30.7; Dresden 30; Berlin 23.5; Leipzig 29.8; Hamburg 29.9; Bremen 21.5; Cologne 32; Frankfurt 18.2; Strasburg 32.8.

For the week ending February 12th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 22.9. Deaths reported 3347: acute diseases of the respiratory organs 408, scarlet fever 71, whooping-cough 70, small-pox (London) 52, measles 37, fever 37, diarrhoea 26, diphtheria 23. The death-rates ranged from 13.4 in Portsmouth to 31 in Oldham; Bristol 17.5; Sheffield 20.5; Birmingham 22; London 23; Leeds 23.5; Manchester 26.5; Liverpool 28.5. In Edinburgh 18.8; Glasgow 27.9; Dublin 41.8.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM FEBRUARY 26, 1881, TO MARCH 3, 1881.

WILLIAM H. ARTHUR, GEORGE E. BRUSHNELL, H. P. BIRMINGHAM and M. C. WYLLIE appointed assistant surgeons United States Army, to rank from February 18, 1881.

AMERICAN MEDICAL ASSOCIATION.—The thirty-second annual session will be held in Richmond, Va., on Tuesday, Wednesday, Thursday, and Friday, May 3, 4, 5, 6, 1881, commencing on Tuesday at eleven A. M.

Sections. Practice of Medicine, Materia Medica, and Physiology: Dr. William Pepper, 1811 Spruce Street, Philadelphia, Pa., chairman. Dr. T. A. Ashby, Baltimore, Md., secretary. Obstetrics and Diseases of Women and Children: Dr. James R. Chadwick, corner of Marlborough and Clarendon Streets, Boston, Mass., chairman. Dr. Joseph Taber Johnson, Washington, D. C., secretary. Surgery and Anatomy: Dr. Hunter McGuire, Richmond, Va., chairman. Dr. Duncan Ely, Nashville, Tenn., secretary. State Medicine: Dr. James T. Reeve, Appleton, Wis., chairman. Dr. R. G. Jennings, Little Rock, Ark., secretary. Ophthalmology, Otolaryngology, and Laryngology: Dr. Dudley S. Reynolds, Louisville, Ky., chairman. Dr. Swan M. Burnett, Washington, D. C., secretary. Diseases of Children: Dr. A. Jacob, 110 West Thirty-Fourth Street, New York, chairman.

Dr. T. M. Rotch, 77 Marlborough Street, Boston, Mass., secretary.

A member desiring to read a paper before any section should forward the paper, or its title and length (not to exceed twenty minutes in reading), to the chair of the committee of arrangements at least one month before the meeting. — By-Laws.

Committee of Arrangements. Dr. F. D. Cunningham, Richmond, Va., chairman.

At a meeting of the New York Academy of Medicine, held January 20, 1881, the following resolution was adopted:—

Resolved, That a committee be appointed by the president to investigate the extent to which leprosy prevails in the United States.

The president appointed as such committee Drs. H. G. Piffard, F. R. Sturgis, and G. H. Fox.

The committee are desirous of ascertaining the actual number of lepers in this country at the present time, and to that end respectfully request any physician who may know of the existence of a case in his neighborhood to communicate the fact to the chairman of the committee, at No. 10 West Thirty-Fifth Street, New York.

BOOKS AND PAMPHLETS RECEIVED.—Cases treated by the Lister Method. Reported to the Portland Clinical Society, 11th of September, 1880. By Frederick Henry Gerrish, M. D. Portland, Me. Privately printed. 1880.

Lectures.

A CLINICAL LECTURE, WITH CASES, ON FOREIGN BODIES WITHIN THE EYE, AND THE ELECTRO-MAGNET AS AN AID TO THEIR DETECTION AND REMOVAL.¹

BY MACDONALD MCHARDY, F. R. C. S., ED.,

Professor of Ophthalmology and Ophthalmic Surgeon to King's College Hospital, London.

THE lens, which has since grown universally opaque, is becoming flocculent, and has not as yet, either by pressure or irritation, occasioned iritis. If the eye remain quiet another forty-eight hours, by which time the cataract will probably be very flocculent, I intend to then remove it by suction, as recommended by Mr. Pridgin Teale. The most opposite opinions exist regarding the merits of this mode of dealing with soft cataracts, as different operators have achieved most opposite results from it. I do not hesitate to recommend it most confidently, as being fraught with exceedingly little danger, provided a properly constructed instrument properly cleansed and disinfected be properly used. Those instruments are best to which the operator's mouth supplies the suction power, as the working of a mechanically contrived suction apparatus must necessarily hamper a hand already fully occupied in the orifice of the curette. The curette portion of the instrument should unscrew so as to admit of its being cleansed more thoroughly than is possible when it is cemented directly on to the glass tube.

You may ask, Why not leave the bricklayer's cataractous lens to be absorbed just as happened in the sawyer's case? You should remember, (1) That the absorption of such a lens would necessarily occupy many weeks, probably months. (2.) That so long as any considerable bulk of the traumatic cataract remains it may swell, press upon, and irritate either the iris or ciliary body, occasioning iritis or cyclitis. (3.) That consequently the organ of vision continues in jeopardy whilst lodging the cataract, and renders the patient unfit to work. Thus there are at least three weighty facts in favor of the most complete and early removal of a wounded lens consistent with safety to the eye.

The concluding number of the last volume of the Boston Medical and Surgical Journal furnishes an interesting report of cases in which Drs. B. Joy Jeffries and Williams successfully utilized the traction of an electro-magnet to facilitate the extraction of steel chips which had penetrated to the aqueous chamber. Dr. Bradford had furnished them with an electro-magnet weighing but four ounces, which when driven by a single bichromate of potash cell sustained five times its own weight at a distance of one inch from the extremity of the core.

Dr. E. Gruening, of New York, after experimenting to concentrate the greatest possible magnetic polarity in the least possible dimensions has finally constructed a permanent magnet of six parallel steel rods somewhat separated from one another with their ends fitted into iron caps, one of which caps terminates with a delicate soft iron stem, thirty-two mm. long by one mm. thick, and three mm. wide, which is capable of sustaining a weight of fifteen grams. The Germans have been using a Janin's magnet, which is a permanent one, composed of layers of watch-spring.

By the introduction of the pointed pole of such an instrument, between the lips of a scleral incision, Fruenkel was enabled to immediately withdraw from the vitreous a concealed fragment of iron, over the suspected position of which he had cut down.

These examples could be easily multiplied, but hoping I have said enough to induce you first to recognize the possible practical utility of magnetic traction in the extraction of chips of iron or steel within the eye, and, secondly, to produce the most handy and powerful electro-magnet, we will pass to the consideration of their use as an aid to diagnosis.

You are all aware that in the presence of iron or steel a delicately balanced magnetic needle is deflected; that a portion of iron or steel whilst magnetized is far more capable than previously of deflecting such a needle; that all steel, and such iron fragments as are not absolutely soft, are capable of being magnetized by induction, that is to say, by remaining in the magnetic circle evolved from a neighboring magnet, with which they need not be in absolute or even approximate contact.

To test the practical applicability of these truths to the diagnosis of the special class of injuries under consideration, I conducted an experiment, of necessity omitting many important but almost impracticable precautions with the bricklayer's eye, whilst it lodged that minute piece of steel in the vitreous. Suspending a delicately balanced magnetized needle with one pole immediately over the chip, I, in vain, endeavored to recognize some deflection of the former. After the chip had been magnetized by induction, and thus rendered more capable of deflecting the magnetic needle, the experiment was repeated with a negative result. Here let me call your attention, as I demonstrated at the time, to the circumstance that if the pole of the magnetic needle be allowed to touch the cornea or conjunctiva the moisture thereon may cause a false deflection, which, unless assigned to the proper cause, might lead to the most erroneous deductions. Dr. Pooley, of New York, who has conducted some very interesting experiments on this aid to diagnosis,² believes that it may prove of real use. Though believing him to be over sanguine on this point, I wish you to know that the negative result furnished by my experiment corroborates his deduction, which was that the test would fail to indicate a magnetized steel chip as small and as deeply placed as that was in the eye of the bricklayer.

For such investigations the needle must be highly sensitive and its deflection often very slight. The delicacy of the needle necessitates its protection from the influence of draughts, and the adoption of some means to neutralize the earth's magnetism, whilst the insignificance of the deflection must be met by some such device as the observation of the reflected light in the focus of a concave mirror mounted on one pole of the magnetic needle. But, after providing all these requirements, how can the influence of jar be neutralized efficiently and consistently with the conditions of such a clinical investigation. These momentous strictures were made upon the occasion of Dr. Pooley contributing a report of his experiments; but an equally cogent and still more serious comment is that even if this method demonstrated two intersecting axes, in which the chip rested, it would not give the third axis needful to fix the position of the chip. However, the method is worthy

¹ Concluded from page 220.

² Vide Knapp's Archives for 1880.

of most careful, intelligent, and patient elaboration; and, until success crown the surgeon's efforts to diagnose intra-ocular fragments of iron or steel by the magnetic needle, recollect and make use of the aid of a powerful electro-magnet in the same direction.

You noted the pain experienced by the blacksmith when his injured eye was well within the magnetic range of the pole of the magnet. That pain enabled him to immediately recognize the completion or interruption of the galvanic current which induced the magnetic action, and therefore furnished conclusive evidence, not only of the lodgment of an iron or steel body, but also that the magnet was exercising a sensible traction thereon. I have used this pain test, with the electro-magnet, on four other eyes in which the presence of iron or steel was suspected; two experienced pain immediately the galvanic circuit was completed, and these upon being enucleated testified the correctness of the diagnosis, that they contained the foreign body, the other two, being unaffected by the magnet, were not enucleated, but dealt with as the nature of the punctured wound demanded. Up to the present, the behavior of each of these preserved eyes has confirmed the diagnosis that the projectile which wounded did not remain in the eye.

The facility which the electro-magnet affords of testing, by the making and breaking of the galvanic circuit, the real as distinguished from the imaginary pain, caused by the proximity of its pole, affords a weighty argument for its selection in preference to the more handy permanent magnet. Moreover, whilst the latter only admits of saturation, the former can be supersaturated.

Quantity, as distinguished from intensity, is needed in the current for working an electro-magnet, and this must be attended to in selecting the battery.

Furthermore, when you experiment to deflect a magnetic needle with a minute influence, do not forget to remove from yourselves, and from the neighborhood, all iron and steel bodies.

Having now narrated my personal knowledge of the value of the electro-magnet as an aid to the removal and detection of iron or steel within the eye, let me ask your best attention to its further development in that direction. Lack of time forbids my entering fully upon the wider subject of foreign bodies in general within the eye. They are very commonly fragments of copper percussion gun caps, and other substances insensible to magnetic influence.

One word of warning in conclusion, when using powerful electro-magnets do not wear a watch lest it be stopped, through the steel therein becoming magnetized, and baffle the skill of the would-be repairer.¹

—Jean Ingelow's Don John is not written for medical readers, judging by the following sentence: "But he had much worse pain to bear before the surgeon had done with him, for it was found that his wrist was badly sprained, and that the small bone of the upper arm was broken." Novelists might with propriety consult their family physicians for the fictitious ailments of their heroes as carefully as for their own material ills.

¹ See the above was delivered, Dr. Wolfe, of Glasgow, has allowed me to test the electro-magnetic apparatus, which has been supplied to him with the permission of its having received Dr. Hirschberg's approval. I have found it to retain some magnetism during a cessation of the current through it, thus evidencing that it is in part a permanent magnet, owing to the employment in its construction of iron that is not pure and soft.

A CASE OF OILY URINE, WITH AUTOPSY.¹

BY E. W. CUSHING, M. D.

K. R., widow, aged fifty-seven, died December 25, 1880. Eleven years ago had severe illness, with fever, delirium, and severe pain in head; otherwise was generally healthy until November, 1872, eight years ago, when she complained of pain in left side, a feeling of swelling and constriction, which continually troubled her.

In spring of 1873 had weakness in left hand, and afterwards in right leg; frequently let things fall from left hand. In June noticed some difficulty in walking, and especially in entering a carriage; also noticed formication in hand and feet, and felt as if walking on air.

In December, 1873, the right hand was similarly affected. She became irritable, could not stand in the dark, stumbled, and fell frequently.

Was examined by a physician, assistant to Professor Bamberger, who pronounced it a case of "tabes dorsalis." In February, 1874, was in bed a week with fever and severe pain in back and head; the sense of constriction persisted, and was very troublesome. She could only lie on left side, walked with staggering gait, fell not unfrequently on attempting to turn suddenly; was nevertheless pretty well as to her general health, and reasonably strong, so as to be about all day. Decided constipation was developed, which required the use of physic every second day during the remainder of her life.

In June made passage to America, traveling with assistance and with some difficulty, especially as to entering cars. In November, 1874, could no longer go up and down stairs; electricity was tried, and was immediately followed by a febrile attack, with much pain in the back. She was seen by Dr. C. Ellis, who pronounced it a case of spinal sclerosis. Such attacks

¹ Read before the Boston Society for Medical Observation, January 18, 1881.

recurred at irregular intervals of about eight months. After each, patient was usually a little more helpless, and after one in 1879 there was ptosis and double vision, lasting for some weeks. In February, 1875, she was unable to leave her bed; this was about two and a fourth years from the first insidious onset of the disease, and not quite five years before her death. The legs soon swelled as high as the knee, the feet were very large and cedematous, so that during all her illness they must be bandaged very carefully to prevent the skin from giving way.

Reflex action in the legs was easily excited, although no voluntary motion was possible, and patient could not tell the position of the legs without seeing them.

In the summer of 1875 a machine was devised to lift her from bed to chair by mechanical power, and she was able to use it until within four days of her death. A platform on castors was attached at one side to a framework, which, when the platform was under the bed, extended over it; proper supports were provided for the hands and feet. A stout piece of canvas, with a suitable hole in the centre, was slipped under the invalid in bed, hooked to the frame by ropes in front, tied round the knees so that it could not slip back, and then, a fall and tackle being hooked to an iron rod in the rear of the canvas, the patient was swung clear of the bed, the whole platform drawn out, the chair placed under the body of the patient, who was then lowered into it, and then the whole apparatus could be rolled to any part of the room.

For convenience in using a wheeled chair, an inclined plane was devised which could be annexed to the rear of the platform.

Thus for five years this poor sufferer passed her life. She could not lie in any position, except on the left side, and then never longer than two hours, without suffering atrocious pains in the back and limbs. Sleep was usually obtained in the sitting position, leaning on a table. The feet and legs grew enormously swollen; there was occasionally some difficulty with the bladder, always relieved by regular catheterization and a little buchu. The hands were tremulous, and could hold no small object, but could manage a spoon or fork; the appetite was good; temper cheerful; intellect serene. There was, however, great sensitiveness to cold, and much suffering from erratic pains, especially in right hip and in legs.

In the summer of 1879 patient repeatedly said that she felt that she should not live long, but seemed about as usual, and was in particularly good health when, just eight years from the first definite symptoms, on November 28, 1880, she was suddenly attacked in the evening with persistent vomiting and atrocious recurrent pains in the left side, in the region of the stomach.

At first it was supposed to be simply a "verdorhener magen," but, as the vomiting continued after the stomach was empty, and the pains grew even more severe, it was thought that it might be a renal calculus or perhaps an intestinal obstruction, and one fourth of a grain of morphine was injected. In the morning about four o'clock there was a very severe rigor, repeated in an hour, but by ten A. M. the pain was much less, and the vomiting was infrequent, watery, somewhat tinged with bile. Soon the temperature began to rise rapidly, and by three P. M. it was 105° F. Dr. Reynolds was called, and when he arrived, by four P. M., patient became totally unconscious, and the temperature in the

axilla was 106.25° F. by accurate and repeated measurements. In the evening (twenty-four hours from the onset) temperature was 103° F.; profuse sweat; patient delirious. The second day temperature 102° F., pulse 120; patient usually delirious; occasional vomiting. The third day the symptoms were the same. The fourth day patient became rational, bowels moved, vomiting ceased, but pulse ran from 120 to 125, at which point it remained for the next two weeks, rising to 130 and 140 as the end approached.

Patient ate well, asking for some solid food. Anasarca commenced to spread over the body and face; there was a steady pain in left hypogastrium. Urine was found to contain pus and mucus, a little albumen, and much phosphatic deposit.

The bladder was washed out with carbolized water, and pain in side relieved by injection of oleate of morphia, fomentations, etc. Pulse always 120 to 130; temperature 102° to 102.5° F. On the thirteenth day there was great pain, referred to rectum; relieved by suppository of opium and belladonna. On the fifteenth day there was an attack of terrific pain in left hypogastrium; patient fairly yelled until brought under the influence of opium in large doses, and from this time until the end morphine was given regularly but moderately *pro re nata*. In drawing the water it was ascertained that the uterus was crowded down, and it was surmised that there was internal suppuration.—probably a perinephritic abscess,—but owing to fatness of patient and anasarca no external tumor could be found, and it seemed very possible that the symptoms of fluid were due to ascites. The urine became acid again, but pus was still evident in it, and some casts were found.

Up to this time the condition of the patient, if serious, had not been hopeless, nor even intolerable; the appetite had been fair, the bowels moved regularly, she was able to sit in her chair for some hours daily; only the high pulse and temperature, and a gradual failure of strength, with the anasarca, told of the internal mischief. From the fifteenth day, however, symptoms of septicæmia developed.

On the sixteenth a profuse diarrhœa commenced, and on the seventeenth great quantities of foul, decomposed pus were evacuated from the bowels involuntarily. There was a chill every morning, and an increase of fever at night, followed by a profuse sweat, great thirst, rapid prostration of strength, and, fortunately, cessation of pain, so that the sufferer was able to lie on her back for the first time in nearly eight years. Great black eschars formed over the left trochanter, and later over the sacrum; no food was taken, except some soup and some milk. There was a continual foul smell in the nose, a subjective symptom merely; the breath was peculiar, pyæmic.

On the nineteenth day a unique phenomenon occurred; the urine when drawn through a catheter (not oiled) was thick, foul, and muddy, and at the end of each catheterization pure, clear oil ran out, in volume about one fifteenth of the urine. This continued during the next three days, with occasional intermissions. It was surmised that the abscess had opened into the urinary tract. A specimen of the urine was shown at the Society for Medical Observation, and was afterwards pronounced to contain oil by Drs. Wood and Fitz.

During these three days the condition of the patient grew rapidly worse. Repeated chills, great prostra-

tion, absolute disinclination for food, repeated involuntary dejections, increase in size of sloughs over sacrum showed the approaching end. On the twenty-third day the urine suddenly became nearly clear, without oil, and continued so until death, which occurred on the twenty-sixth day, after twenty-four of unconsciousness.

The autopsy was made thirty-eight hours after death by Dr. A. N. Blodgett, in the presence of Drs. Reynolds, Fitz, Ellis, and Cushing.

The cord was first removed, and showed patches of sclerosis.

Foul pus and oil were encountered in the left lumbar region, while sawing the spine.

On opening the abdomen a large, foul collection of pus, containing an abundance of free oil and large strings and pieces of sloughing fat, was encountered in the left abdominal and iliac region. It was external to the peritoneum, lying among the fatty tissue. The neighboring coils of intestine were glued to the peritoneum nearest the abscess. Over one and a half pints of this pus were sponged out, the intestines, bladder, and kidney removed in a mass and examined. The kidney was a long one, a so-called horseshoe, reaching across the spine, and having a long pelvis, with two ureters. The pelvis showed diphtheric inflammation, and near the exit of the left ureter was a small opening communicating with the abscess. A larger opening through a mass of sloughy tissue joined the cavity of the abscess with the intestine. There was evidence of diphtheritic cystitis.

The chest and head were not examined.

As far as the symptom of oil in the urine, occurring in any such quantity, goes, the case is unique so far as I can learn. The only lesson of importance which could be drawn from this symptom, if it be again observed, seems to me to be that it is a sign not only of an abscess opening into the urinary tract, but moreover that there is sloughing going on sufficient to set free the oil of the fatty tissue, and sure to terminate fatally, unless by free opening and counter-opening a very free drainage and disinfection can be carried out.

The following letter has been received from Professor Wood:—

DEAR DR.,—I shall not be able to be present to hear your case of oily urine at the Observation Society to-morrow evening, and therefore send you the following items in regard to my examination of the specimen which you gave to me at the former meeting. The urine had become alkaline, and when placed in a graduated vessel the oily fluid occupied one fifth of the total volume. The microscope showed triple phosphate, urate of ammonium, oil, and numerous crystals of fatty salts, due partially to the saponification of some of the oil by the ammonia.

This sediment, so far as the fatty elements were concerned, had the same appearance as represented in Funke's Atlas, Taf. VI., Fig. 4, Fettkrystalle aus saurem Eiter.

I found no extraneous elements in the urine which would tend to show any direct connection with the intestine.

The case is, so far as I have been able to look it up, a unique one, and I am very glad that you are to report it. Very sincerely yours,

EDWARD S. WOOD.

Boston, January 16, 1881.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M. D.

OSTEOLOGY.

A THIRD OCCIPITAL CONDYLE.¹

Dr. ALLEN begins his paper, in many respects an interesting one, with the following description of the anomalous process which he had observed on an adult female skull:—

"This tertiary condyle is in the form of a conical process of bone, about two fifths of an inch in depth, directed downwards from the anterior edge of the *foramen magnum*, and bearing posteriorly a vertical transversely concave articular surface, which extends superiorly to the upper level of the basilar process." In three other cases which Dr. Allen examined the condyle is merely an articular facet on the border of the *foramen magnum* and does not project downwards. When it exists only to this extent it may easily be overlooked.

Dr. Allen concludes that "the third occipital condyle which is occasionally seen in the human subject, corresponds to the intervertebral surfaces of the vertebral centra, and is also the morphological representative of the central element of the single avian and reptilian condyle." Also that "the abnormal articular surface is associated with growth upwards of the odontoid process, and is not the result of any change beginning primarily in the cranium."

This lengthening of the odontoid, Dr. Allen believes to be the result of over-extension of the head in utero, whereby the end of the odontoid is relieved from pressure. This view rests in part on what he saw in a median section of a mature fetus in which the odontoid was decidedly lengthened and articulated with the occiput.

PECULIARITIES OF THE SQUAMOUS PORTION OF THE OCCIPITAL BONE.²

Ten years ago Professor Merkel called attention to a third transverse ridge on the posterior surface of the occipital bone. He still called the original superior line by its old name, and the new one the *suprema*. It is not, we believe, always present, though it certainly is far from rare, and a hint of it may be seen in the illustrations of several anatomies that contain no mention of it. Its relations to the superior line are uncertain. There may be a depression or an elevation between them or they may both appear as the edges of a transverse prominent ridge which has been named the *torus occipitalis transversus*. Other anatomists have discussed the anthropological significance of this structure, and the last of these is Professor Waldeyer. We will quote from his conclusions from which an idea can be gained of the views that others have held. "It follows from these observations that the torus occurs more frequently among Europeans than would be inferred from the publications before us. Further, that it is not a peculiarity of a race in which it occurs without exceptions, . . . and finally that in itself it should not be considered the *characteristic* of a low race, for it seems to be very rare in negro skulls and is found with remarkable frequency in European skulls of the present time. We do not, of course, mean by this to deny the

¹ Tertiary Occipital Condyle. By William Allen, M. D. *Journal of Anatomy and Physiology*, October, 1880.

² Waldeyer, *Archiv für Anthropologie*, Band xii., 1880.

anthropological value of the *torus occipitalis*, which may well be claimed for it as an ape-like formation. Moreover, as certainly must be admitted, it is much more common in prehistoric skulls and in those of lower races, so it is still an important sign which, in connection with others, may permit us to assume the low character of a skull." It should also be mentioned that Waldeyer gives drawings of two skulls, one of a child at birth, and the other of a six months' fetus, on both of which the three lines can be made out. This is of consequence, as they had not previously been described as present at so early an age.

ANOMALOUS LUMBO SACRAL VERTEBRA.¹

Plenty of observations have been made of late years on an extra vertebra in the lumbo-sacral region which may appear as a sixth lumbar or as a first sacral, or as a nondescript piece which might be described as wanting the definite characteristics of either, rather than combining those of both. We may find, however, that the lowest lumbar vertebra possesses such distinct sacral characteristics that if we examine it only from the front we may doubt in which region it should be placed, and thus, though we have a peculiar vertebra, we do not have an additional one. From the very various appearances it presents, we are rather inclined to believe that this piece may occur in very various ways and may have more than one signification. The last writer on the subject is Dr. Wilhelm Raab. He holds that the anomaly is really a modification of the last lumbar vertebra and implies that the essential change is the association and development of the ilio-lumbar ligament into a lateral piece of the sacrum. He believes this to be a homologue of the ribs, which seems to us very possible. The important part of the communication is that which shows the effect of this process on the figure when it occurs only on one side. The capacity of the pelvis is less on that side than on the normal one, the distances from the sacrum to the pubes and to the hip-joint being decidedly lessened. The ileum is higher on the affected side and thus the corresponding leg is, according to the author, apparently shortened. The difference is found more marked in the older subjects. If the assimilation occurs on both sides this apparent asymmetry does not occur, but the iliac crests are higher on both sides than usual, and the sacrum presents two promontories. We do not think that this curious question is by any means settled, but it is worth while to know of another cause of real inequality in the length of the legs. We know from the numerous measurements taken of late years that the bones are very frequently of different lengths, so much so, indeed, as to make our stock of observations on shortening after fracture practically worthless, and now we have another cause of asymmetry. It would be interesting to know whether the longer leg is not sometimes found on the side on which the pelvis is placed higher.

COALESCENCE OF THE BONES OF THE FOOT.²

Dr. Zuckerkandl, the indefatigable prosector at Vienna, reported some years ago a case of synostosis of the astragalus and the calcaneum of both feet. He has now observed two other cases in which it occurred on one side, the first in a boy of ten, the second in a grown

man. In all the cases, the coössification was between the astragalus and that part of the calcaneum known as the *sustentaculum tali*. In both cases reported in the paper before us the head of the astragalus, and consequently the foot, was strongly rotated inwards. The author points out that this synostosis could hardly be acquired by a person who walked on account of the movements in the inter tarsal joints, and further that the position of the foot is precisely the opposite of the one that the foot could assume in bed. It is not reasonable, therefore, to look on this as a result of disease, but rather as caused by an arrest of development, to wit, of the formation of the joint between the bones in question. This view is strengthened by the appearances of the other foot of the boy. There was no union there between the bones, but the smooth articular surface on the sustentaculum was small, and the neighboring opposed surfaces were rough, and resembled strongly those between the end of the shaft and the epiphysis of a long bone when they have been separated by maceration. Clearly such an arrangement must greatly check motion. In at least one of these cases, that of the boy, the sole was abnormally flat, and Zuckerkandl suggests that this, together with the loss or great diminution of the foot's power of rotation, might point to this condition in the living. He further believes that under these circumstances the step must lose some of its elasticity. He gives a largely magnified drawing of a vertical transverse section of the foot of a two months' fetus which seems to show that the joint above the sustentaculum tali is formed at a later period than the other joint below the astragalus and the one above it. He mentions in the same paper another anomaly which is probably very rare; but is of interest as it would make it impossible to perform Chopart's amputation. This consists in a firm connection of the inner part of the front of the calcaneum with the outer end of the scaphoid. The band was formed of an uncommonly tough fibrous tissue, covered in front with cartilage, so that the cartilage of the scaphoid articulation passed without change of level into that of the heel-bone. Thus there was a continuous articular surface for the three cuneiform bones and for the cuboid. The former set of observations seem to us of great importance in regard to the etiology of club-foot. May it not be that in some cases the primary cause is the arrest of the process of separation between neighboring bones?

Hospital Practice and Clinical Memoranda.

BOSTON LYING-IN HOSPITAL.

CASES IN THE SERVICE OF DR. W. L. RICHARDSON.

REPORTED BY R. A. KINGMAN.

I. DEFORMED PELVIS. INDUCTION OF LABOR.

M. G., twenty-two years of age, single, primipara, born in Maine. This patient entered the hospital November 20, 1880, to await confinement. Catamenia ceased late in February or early in March. She states that when four years old she fell down stairs and received an injury to the spine. On examination there was found a spinal curvature involving the four lower lumbar and first sacral vertebrae. The curva-

¹ The Occurrence and Signification of the Assimilation of the last Lumbar Vertebra with the Sacrum. *Medizinische Jahrbücher*. 1880, Heft 1 and 2.

² *Medizinische Jahrbücher*, 1880, Heft 1 and 2.

ture was regular in outline and of considerable prominence.

External measurements of pelvis:—

Between anterior-superior spines of ilia .	8 $\frac{1}{4}$ inches.
Between the crests of the ilia	9 inches.
Antero-posterior diameter	6 $\frac{7}{8}$ inches.
Antero-posterior diameter of the inlet (internal measurement)	3 $\frac{1}{4}$ inches.

The pubic arch was much narrowed. The abdominal tumor stood out at nearly a right angle from the body, and was almost entirely anterior to the plane of the sternum. Patient's height was 4 feet 6 $\frac{1}{2}$ inches.

It was decided to induce labor by means of manual dilatation.

The following day ether was administered at 10 A. M. Dilatation was commenced at 10.30, but, after a trial of ten minutes, it was discontinued as being impracticable, the pubic arch being so narrow that the hand could not be accommodated, and a dangerous amount of pressure was being exerted upon the labia.

At 10.45 A. M. a catheter was introduced between the uterine wall and the membranes and fixed in position by means of a stylet and bandage around the waist. A pain came on before the patient was fully out of the ether. At 1.30 P. M. the catheter was removed, the pains being then quite strong and frequent. During the afternoon the pains grew weaker and occurred at longer intervals. Patient vomited frequently after recovering from the ether.

In the evening the labia were found to be much swollen. A warm carbolyzed douche was ordered to be repeated every three hours. 11 P. M. Pulse 94; temperature 98.6° F. Cervix nearly taken up. Has slept most of the time for the past hour. Pains very infrequent. Nausea and vomiting continue. (Sodæ bicarb. ℥i., ol. absinth. gtt. iij., aquæ ℥ij., M. ℥ss every three hours was ordered.)

November 22d. 2.15 A. M. Morph. sulph. gr. $\frac{1}{4}$ subcut., followed by sleep during the remainder of the night. 10.30 A. M. Pulse 90; temperature 98.4° F. No pains this morning. Catheter again introduced between the uterine wall and membranes. Nausea and vomiting continue. 2.30 P. M. Chill. Has vomited as often as once in fifteen minutes during the last three hours. Temperature 99.3° F. 3 P. M. Pains infrequent but severe. The last one lasted six minutes. 8.05 P. M. Catheter removed, and membranes artificially ruptured. Pains occur every ten minutes. Cervix taken up. Os one half inch dilated. The uterus has been extremely hard all day, as though in a state of partial tonic contraction. 10 P. M. Os fully dilated. Head presenting O. R. A. 11 P. M. Head kept from descending by the narrow arch. Ether was given, and forceps were applied at 11.25 P. M. The child was born at 11.35 P. M., and was apparently of about seven and one half months' growth. It was resuscitated with much difficulty. Male, four pounds. 11.40 P. M. Placenta expressed. Perineum deeply lacerated. Three catgut sutures were inserted. Ergot ℥j. No hemorrhage. In half an hour the pulse was 150. Urine acid, sp. gr. 1015. No albumen.

November 23d.¹ Pulse 111. Temperature 100° F. Quite comfortable. No vomiting. Baby died at 8.30 A. M. Pulse 118. Temperature 102° F. Headache. Intra-uterine douche daily. Vaginal douche every

¹ Temperature and pulse taken daily at 8.30 A. M. and 5 P. M. in all these cases, hence the double record.

three hours, followed by the insertion of a vaginal tampon saturated with carbolyzed vaseline. Vulva dressed with same. Milk and lime-water *ad libitum*.

November 24th. Pulse 114. Temperature 99.8° F. Treatment as yesterday. Uterus large and very tender. Pulse 111. Temperature 101.1° F.

November 25th. Uterus smaller and less tender. Two intra-uterine carbolyzed douches. Pulse 108. Temperature 99° F. Pulse 123. Temperature 101.1° F. Seidlitz pulv. no. ij. enema.

November 26th. Pulse 114. Temperature 98.4° F. One intra-uterine douche. Bromide gr. xx., chloral gr. x., at eleven P. M. Pulse 120. Temperature 100.8° F.

November 27th. Pulse 121. Temperature 100.4° F. Painful micturition. Pulse 117. Temperature 101.2° F. Bromide gr. xx. at seven and nine P. M. Urine, odor very offensive, sp. gr. 1025, neutral, albumen one eighth per cent. Sediment contains pus, epithelium, and bacteria.

November 28th. Pulse 108. Temperature 98.7° F. Bladder washed out with carbolic solution. Intra-uterine douche discontinued. Pulse 111. Temperature 99.5° F. From this time the patient made steady improvement up to the time of her discharge, having no marked rise of temperature and complaining of nothing but the painful micturition. She was placed upon saleratus water, *ad libitum*, for four days, by which time all bladder symptoms had disappeared.

December 6th. Patient sat up for the first time.

December 10th. Examination showed that the perinaeum had not completely united, and the torn surface had not wholly healed. Depth of uterine cavity two and one half inches. Local applications were made to the unhealed surface of the perinaeum, and the patient was discharged well December 15th.

II. ACUTE JAUNDICE.

A. T., twenty-four years old, married twice, multipara, born in Massachusetts. After her previous confinement in the hospital, June 19, 1879, patient had puerperal mania. Catamenia last seen May 10th. November 26th entered in labor. Has had pains all day, her attending physician having given morphia without effect. For the past two or three weeks patient has suffered from headache, nausea, and vomiting. Her skin is deeply jaundiced; and this symptom she has noticed for the past four days. Palpation: Breach in fundus to right; fetal heart not heard; fundus two inches below ensiform cartilage. Per vaginam: vagina normal; cervix not quite taken up; os easily admits the finger.

The labor progressed rapidly, lasting only about five hours. The child was a female, weighing three and one half pounds. It was immediately swathed in cotton, and kept warm by means of heaters. Urine, acid; specific gravity, 1025; albumen, a trace. The color was very high, owing to biliary pigment present.

November 27th. Pulse 82. Temperature 97.6° F. Bromide gr. xx. at 3.30–6–10 A. M. 2–5–8–11 P. M. Pulse 90. Temperature 97.6° F.

November 28th. Pulse 88. Temperature 98.4° F. — Pulse 101. Temperature 100° F. Hemierania of right side instead of left as heretofore. Itching of skin. Jaundice increasing. Bromide gr. xxx. at 10–1–4–7–10 o'clock. Calomel gr. v., jalap gr. vi. M. At nine P. M. Ice-water to head.

November 29th. Pulse 106. Temperature 98.7° F.

Two dejections last night, of a clay color. Pulse 110. Temperature 100.8° F. \mathfrak{R} Sodæ bicarb. \mathfrak{z} i., ol. absinthii gtt. iij., aquæ \mathfrak{z} ij. M. \mathfrak{z} ss. was given at 12-3-6. Bromide continued. Chloral gr. x., 11 p. m.

November 30th. Pulse 84. Temperature 98.8° F. — Pulse 84. Temperature 100.4° F. Breasts tense and painful. Rubbed with camphorated oil and strapped. Calomel gr. v., jalap gr. vi., 11 a. m. Bromide continued. Chloral gr. x., 9-10.30 p. m. Morphia suppository gr. one fourth at 11 p. m. Ice-water to head continued.

December 1st. Pulse 114. Temperature 102° F. Lochia somewhat excessive. Cried most of the time last night, and refused her medicines. Tore the bandages from her breasts. Refuses to eat. Seems rational but cross. Pulse 94. Temperature 100.2° F. Same treatment continued. Calomel gr. v., jalap gr. vj. Chloral gr. x., 9 and 10 p. m. Has passed a comfortable day.

December 2d. Pulse 100. Temperature 100° F. Slept soundly all last night. Feels nicely. Pulse 94. Temperature 102° F. Soreness of gums. Yellow dejection. Jaundice lessening. Bromide continued. Chloral gr. x., at 10 p. m.

December 3d. Pulse 104. Temperature 99.1° F. Slept well last night. Pulse 100. Temperature 100.8° F. Bromide continued. Chloral gr. x., 9 and 10 p. m.

December 4th. Pulse 104. Temperature 99.6° F. Gums still sore. Tannic acid mouth wash. Pulse 90. Temperature 100.6° F. Bromide gr. xx. Chloral gr. xv., 9 p. m.

December 5th. Pulse 108. Temperature 99.8° F. Lochia have ceased. Pulse 108. Temperature 100.2° F. Hunyadi water, \mathfrak{z} iv. before breakfast. Tannin mouth wash continued. Intra-uterine douche.

December 6th. Pulse 102. Temperature 100.2° F. — Pulse 108. Temperature 102° F. Patient very cross and refractory. Was moved to small room, where she will be alone. Lochia reëstablished.

December 7th. Pulse 100. Temperature 99.6° F. — Pulse 100. Temperature 100.1° F. Patient moved back to general ward on promise of good behavior.

December 8th. Pulse 76. Temperature 99.2° F. — Pulse 80. Temperature 99.8° F. Sat up. Mouth nearly well.

December 9th. Pulse 96. Temperature 98.2° F. Jaundice has entirely disappeared except on the conjunctivæ.

December 13th. Examination. — Perinaum intact; cervix somewhat lacerated; depth of uterine cavity two and three quarters inches. Discharged mother and child well.

III. ECLAMPSIA, ACUTE PARENCHYMATOUS NEPHRITIS, MANUAL DILATATION, VERSION.

M. McG., nineteen years old, married, multipara. Born in Cambridge. Catamenia ceased in April. Patient entered the hospital December 17th, having had a convulsion December 12th. The following is an extract from a letter received from her physician, who attended her in her former confinement:—

"In her first confinement she had albuminuria with severe convulsions. I delivered her with forceps. The occiput swept the perinaum and ruptured it partially through the sphincter ani. It was carefully sewed up at once, but failed to unite. After a time she regained control of the faeces, and declined to allow further op-

eration. In the present pregnancy, when three or four months advanced, she took a lot of oil of tansy. She had several severe convulsions, and was unconscious several hours."

When admitted to the hospital patient was put immediately to bed, and was constantly watched. She appeared stupid, lay with eyes closed, lids constantly vibrating slightly, and hands tightly clenched. Would rouse if spoken to sharply. At 10.30 p. m. the catheter was passed, and \mathfrak{z} ij. of urine obtained, none having been passed since two a. m. Reaction, acid; albumen, two per cent.; fine granular casts. 1.15 p. m., vomited; 2.30 p. m., had a severe convulsion, lasting about one minute. Ether was administered the moment the convulsion commenced, and the patient was afterwards kept under its influence.

Artificial delivery having been decided upon, manual dilatation was commenced at 3.55 p. m., and was completed in sixty-five minutes (five p. m.). The operation was attended with considerable difficulty, owing to a low attachment of the placenta, a small piece of which was torn off, giving rise to considerable hæmorrhage. At five p. m. distinct uterine contractions commenced. The membranes were ruptured a few minutes later, and the child was extracted by version, forceps being applied to the after-coming head. At 5.15 p. m. the child was born, and was resuscitated with some difficulty. It was a girl, and weighed five pounds. Five minutes later the placenta was expressed, and ext. ergot. \mathfrak{ss} . administered. Considerable hæmorrhage occurred, and the uterus contracted only after a hot intra-uterine douche. Pulse 145.

Previous to the convulsion patient had received cream-of-tartar water *ad libitum*, also spts. æth. nitrosi \mathfrak{z} i. in water every two hours. This was recommenced after the labor, and continued through the night. 3.30 p. m. Catheter passed. Urine \mathfrak{z} viiss. Albumen one per cent.

December 18th. Pulse 88. Temperature 97.2° F. Slept well after one a. m. Vomited at six o'clock. Pulse 120. Temperature 103.6° F. Skin very hot and dry. Patient lies in state of stupor, from which she can be aroused by speaking sharply. Same treatment continued. The catheter was used at frequent intervals, and the following are the amounts of urine drawn: Seven a. m., \mathfrak{z} ij.; albumen one per cent. 11.30 a. m., \mathfrak{z} ij.; albumen one per cent. 1.50 p. m., \mathfrak{z} v.; albumen one half per cent. 4 p. m., \mathfrak{z} v.; albumen one half per cent. 5 p. m., \mathfrak{z} iss.; albumen one half per cent.; epithelial, hyaline, fine granular casts. 7 p. m., \mathfrak{z} v.; albumen one fourth per cent. 9 p. m., \mathfrak{z} iv.; albumen one fourth per cent.

December 19th. Pulse 108. Temperature 99° F. Restless during the night. Feels much better this morning. Baby died. Pulse 124. Temperature 103.4° F. Amounts of urine obtained by catheter: One a. m., \mathfrak{z} v. 4.30 a. m., \mathfrak{z} vss. 9 p. m., \mathfrak{z} v. 11 a. m., \mathfrak{z} ivss.; albumen one half per cent.; casts. 1 p. m., \mathfrak{z} ijss.; one half per cent. 4 p. m., \mathfrak{z} vij. 6.30 p. m., \mathfrak{z} vss. Skin hot and dry. Headache. Same treatment continued. Intra-uterine douche at 7 p. m. Much offensive matter came away.

December 20th. Pulse 88. Temperature 97° F. Lochia offensive. Skin cool and moist. Mental condition much improved. Appears perfectly rational. Intra-uterine douche at 5 p. m. Pulse 100. Temperature 100.6° F. During the day patient has passed \mathfrak{z} xxix. of urine; albumen one half per cent.

December 21st. Pulse 112. Temperature 100.4° F. — Pulse 112. Temperature 101.2° F. Milk in breasts. The latter tense and painful. Breast supporter (as

shown in the plate) applied with great relief. Lochia offensive. Intra-uterine douche twice. During last night passed \bar{x} of urine. During the day \bar{x} vi. of urine; albumen one half per cent.; casts very few. Nitre and cream-of-tartar water continued.

December 22d. Pulse 112. Temperature 100° F. Very restless all night. Sleeping this morning. Pain in right leg. Cream-of-tartar water continued. Nitre omitted. Intra-uterine douche. Urine during last night and to-day \bar{x} xxxiijss.

December 23d. Pulse 100. Temperature 99.6° F. — Pulse 100. Temperature 100° F. Is much brighter this morning. Headache in afternoon. Albumen one half per cent.; few casts.

December 24th. Pulse 96. Temperature 98.4° F. — Pulse 80. Temperature 98° F. Very bright and talkative. Albumen one fourth per cent.; very few casts; amount normal. December 25th. Pulse 96. Temperature 97.6° F. — Pulse 104. Temperature 100° F. Albumen a trace; no casts. December 26th. Pulse 86. Temperature 98° F. — Pulse 100. Temperature 100.6° F. Intra-uterine douche. December 27th. Pulse 92. Temperature 99.2° F. — Pulse 80. Temperature 98° F. Intra-uterine douche at 11 A. M. Cream-of-tartar water. December 28th. Pulse 92. Temperature 98.4° F. — Pulse 92. Temperature 100.8° F. December 29th. Pulse 116. Temperature 103° F. Headache. Sleep disturbed last night by a confinement in the same ward. Sleeping this morning. Lochia all right. Evacua at 11 A. M. Intra-uterine douche. Pulse 112. Temperature 103.2° F. December 30th. Pulse 112. Temperature 99.8° F. Did not sleep well last night, on account of talking in the ward. Feels nicely this morning, however. Pil. cath. comp. No. ij. at 12 M. Pulse 108. Temperature 102.2° F. December 31st. Pulse 120. Temperature 101.2° F. Urine acid; albumen one fourth per cent.; no casts. Nitre \bar{x} every three hours. Pulse 136. Temperature 104.6° F. January 1st. Pulse 100. Temperature 99.4° F. — Pulse 94. Temperature 103.2° F. Nitre and cream-of-tartar water continued. Urine, amount normal; albumen one fourth per cent.; casts present. January 2d. Pulse 99. Temperature 99.8° F. — Pulse 92. Temperature 101° F. January 3d. Pulse 98. Temperature 99.6° F. — Pulse 94. Temperature 102° F. Complaints of pain in the back. January 4th. Pulse 96. Temperature 98.8° F. — Pulse 100. Temperature

101° F. Tr. ferri chloridi gtt. xx. t. i. d. to be continued. Nitre and cream-of-tartar water stopped. January 5th. Pulse 90. Temperature 99.5° F. — Pulse 90. Temperature 99.4° F. Sat up. January 6th. Pulse 80. Temperature 98.4° F. — Pulse 80. Temperature 99.8° F. January 7th. Pulse 80. Temperature 97° F. — Pulse 72. Temperature 99.2° F. Doing well. January 8th. Pulse 84. Temperature 98.2° F. January 10th. Urine acid; specific gravity 1018; albumen, trace. Sediment. Renal epithelium, mucus, hyaline, and fine granular casts.

January 15th. Examination showed the depth of the uterine cavity to be two and a half inches. Old laceration of perinaeum; double laceration of cervix, with anteversion of uterus. Discharged, well.

The breast supporter was invented by Mr. Kingman and has been used in many cases in the hospital with great relief to the patients.

IV. EXCESSIVE THIRST AND POLYURIA OCCURRING DURING PREGNANCY.

A. C., aged twenty-four years, single, primipara, born in Boston. Patient entered the hospital December 14th. While awaiting confinement it was noticed by the night-nurses that the patient drank large quantities of water. She was confined December 20th, having a normal labor, and gave birth to a healthy male child weighing seven pounds. Urine much increased, slightly acid, specific gravity 1003, no albumen.

Patient complains of constant thirst, and drinks very frequently. The amount of liquid supplied to her was carefully measured, as was also the amount of urine passed. The results of this measurement may be seen in the table below, the figures representing the number of fluid ounces during the twenty-four hours ending at noon of each day. The morning and evening pulse and temperature may also be found in the same table. This great thirst came on when about three months pregnant, and continued unabated until after her delivery, when it gradually ceased.

December 23d. Patient had headache, nausea, and offensive lochia. An intra-uterine douche was given at seven P. M., followed by frequent vaginal douches during the night. Quinia gr. x., 9 P. M.

January 6th. Discharged, mother and child well.

New Instruments.

AN IMPROVED EAR-SPOUT.

EDWARD J. FORSTER, M. D., CHARLESTOWN, MASS.

THE annexed cuts represent both the common ear-spout as sold by the instrument dealers and as improved by me. As ordinarily made its *raison d'être* is difficult to discover, for it does not in the least obviate the use of the basin unless the patient wears a rubber suit.

The basin has the disadvantage of often being in the way of the syringe, and as usually made, unless it is held steadily and in a horizontal plane, its contents are apt to be spilled.

By adding to the common spout a shield in front and having a tin tube and the necessary length of rubber tubing attached to its lower extremity we have an instrument by which the ear can be syringed without danger of wetting the clothes. The patient holds it readily to the ear and the rubber tubing conducts the water to a receptacle placed in any convenient position.

The spouts can be obtained of Messrs. Leach & Green, 1 Hamilton Place, Boston.

22 MONUMENT SQUARE, February 12, 1881.

AN IMPROVED POCKET-CASE.

BY FRANCIS H. BROWN, M. D.

MANY of the pocket-cases furnished by surgical instrument makers are clumsy, some have instruments too small to be easily handled, some are lumbered up with appliances which are obsolete or have been supplanted by more convenient patterns, and most of them are sadly wanting in just what the surgeon needs in his every-day work. One of our neighbors carries only a lancet; he borrows a knitting needle when he needs a probe; a gum elastic male catheter is in his carriage; and scissors, needle, and sewing silk are to be found in every lady's work-basket. To those, however, who wish to be provided with their own individual tools, a well appointed case is at once a comfort and a necessity.

I believe the combination which is here offered, and which has been put up by one of our instrument makers, will more nearly meet the needs of the average medical practitioner than any other in the market.

The case itself is known as the cigar-case pattern; it has a metal skeleton to give it firmness and prevent the warping and distortion so soon experienced in cases made entirely of leather.

The first knife (in a turtle shell handle) is a small amputating knife, with a blade, from pivot to point, of about ten cm. (nearly four inches). With this a country physician, at a distance from his home, can, in an emergency, and with a borrowed back-saw, do any amputation, except of the thigh. Three double knives, in handles 10.5 cm. (about four and one fourth inches) long, are thus combined; scalpel and Newman's can-

ulated needle; gum lancet and tenotome; probe and sharp-pointed curved bistouries. Tiemann's shorter bullet forceps, the best possible form for dealing with bullets, serves admirably for impacted foreign bodies in the ear, and for the general purposes of dressing forceps. A slide catch dissecting, artery, and needle forceps is of general utility, a hard-rubber porte caustique, sixteen cm. (six and one half inches) long, with Tiemann's combined trocar and canula, scissors, female catheter, director and aneurism needle (in one) two probes, Evans's lancet, surgeon's needles, silk, and adhesive plaster complete the list. A subcutaneous syringe, made to correspond in size and shape to the common stylographic pen, can be introduced.

The special points claimed are the case, the amputating knife, and the bullet and dressing forceps.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

A. T. CABOT, SECRETARY.

JANUARY 3, 1881. Dr. DRIVER read a paper upon Relaxation of the Pubic Ligaments. He recounted several cases of this condition which had occurred in his practice, and in which his attention had been called to the relaxation by the symptoms. The patients at times felt the slipping of the bones upon each other, and the insecurity of the gait was always marked.

Believing that laxity of the pubic ligaments after child-bed was a more common condition than is generally supposed, Dr. Driver examined sixty successive cases of midwifery with reference to this point.

A slight degree of relaxation was found in a considerable proportion of the cases, and in one or two of them the laxity was quite marked.

Dr. F. H. DAVENPORT said that the theory that relaxation was caused by the pressure exerted by an unusually large head in its passage was disproved by many observations. A most striking fact in opposition to this view is that an extreme degree of laxity has been observed after an abortion at four months. He asked Dr. Driver's experience upon this point.

Dr. DRIVER said that in some of the hardest of his labors there had been no separation, while in some easy labors there had been much.

JANUARY 17, 1881. Dr. MORRILL reported a case of severe laryngeal spasm in an infant relieved by an incision into a mass of suppurating cervical glands.

Dr. T. B. CURTIS suggested that the alarming symptoms of glottic spasm, occurring in paroxysms and terminating in a deep, prolonged inspiration, described by Dr. Morrill, and so successfully relieved by his timely and efficacious surgical intervention, were perhaps amenable to another interpretation, as regarded their pathological physiology, than that brought forward by the reader. Instead of a direct irritation of the recurrent nerves occasioning laryngeal spasm, Dr. Curtis would rather be disposed to attribute the disturbances observed in this case to an irritation of the superior laryngeal nerves, exerted by the pressure of the enlarged glands, and causing reflex disturbances of the respiratory movements. Such is the accepted explanation of the symptoms which characterize *laryngismus stridulus* or "spasm of the glottis," a neurosis

related to *celampsia*, often associated with tetany, occurring mostly in infants under one year of age, especially when syphilitic or rickety, and proving fatal in a very large proportion of the cases in which it takes place. Laryngismus may also occur as a fatal complication of whooping-cough, and then constitutes an exaggerated degree of one of the usual phases of the paroxysm, in which the deep inspiration, which should succeed the convulsive expiratory efforts constituting the coughing fit, fails to take place.

The disturbances observed in laryngismus stridulus consist in a more or less prolonged cessation of the respiratory movements, the muscles concerned in the latter being immobilized in the attitude of extreme expiration, with closure of the glottis, tonic spasm of all the expiratory muscles, and relaxation of the diaphragm. The face is congested and, perhaps, cyanosed; the veins of the neck are turgid. This condition may be so prolonged as to cause death by asphyxia; or it may terminate favorably in a deep inspiration or in a series of short, jerky inspirations, which are considered pathognomonic indications of laryngismus stridulus.

This interpretation of the symptoms observed in such cases is in accord with what we know of the physiology of respiration. The vagus is at once a sensitive and a motor nerve. The muscles of the larynx are all animated by the centrifugal motor fibres contained in the recurrent nerves, with the single exception of the crico-thyroid muscles, which are innervated by branches of the superior laryngeal nerves. The latter are mainly sensitive or centripetal, and are distributed to the mucous membrane of the larynx. According to the experiments of Rosenthal, whose results have been confirmed by many other investigators, irritations of the superior laryngeal nerve cause inhibition of the inspiratory stimulus supplied by the respiratory centre in the medulla oblongata, and positive stimulation of the expiratory forces. The results of such an experimental irritation are closure of the glottis, tonic spasm of the expiratory muscles, and relaxation of the diaphragm. *Spasm of the diaphragm* has been supposed to occur in some cases of laryngismus. Such a disturbance would, however, not be in accord with the teachings of physiology, nor would the deep, sonorous inspiration, which is said always to announce the termination of the paroxysm and the re-establishment of normal respiration, be possible, were the diaphragm already in a state of spasmodic contraction.

A disease to be carefully distinguished nosologically as well as clinically from laryngismus is *stridulous laryngitis*, commonly called "croup" or "false croup." The latter consists merely in a laryngo-tracheal catarrh, occurring in children several years old, and complicated by nocturnal paroxysms of transient laryngeal spasm. This form of laryngeal dyspnea, though often alarming to witness, is probably never fatal, and is readily relieved by Graves' method of treatment, consisting in sponging the throat with hot water, or else by an emetic dose of ipecac or apomorphia.

Dr. MORRILL, in reply to Dr. CURTIS, said that the symptoms in his case, however they might be accounted for theoretically, certainly resembled those present in thymic asthma. He was sure, however, that the case did not come under this head, as the child had never had a previous attack, nor had any occurred since the one referred to, a space of nearly a year. The symptoms were of most alarming character, and far more intense than those present in simple

spasm of the glottis, which is so readily relieved by the application of a hot sponge or the administration of an emetic. He felt quite sure that any delay in making an opening in this case would have proved fatal.

Dr. KNIGHT said that the question in diagnosis would be between spasm of the adductors and paralysis of the abductors of the vocal cords. He thought from the history of the symptoms and the rapid relief by the operation that Dr. Morrill was probably correct in his diagnosis of spasm, though this case recalled one which he had seen in the practice of Dr. J. G. Blake, and which had been reported to this society, in which paralysis of the posterior crico-arytenoid muscles occurring in a case of diphtheria was quickly relieved by tracheotomy. Dr. Knight, *apropos* of spasm of the glottis from irritation of the sensitive nerve of the larynx (superior laryngeal), said that he had observed a mild form of spasm in the laryngeal catarrh of old people.

Dr. BLODGETT showed a rare monstrosity. The child still-born, had, to all external appearances, but one body with two heads, one hydrocephalic, the other anencephalic. The case will be published in full.

Dr. CUSHING reported a case of oily urine.¹ At a previous meeting of the society Dr. Cushing had shown a specimen of this urine, which was covered by a thick layer of oil. The patient, having since died he was now able to describe the post-mortem appearances, which fully explained the presence of oil in the urine. In connection with the case the reader showed a very efficient apparatus, devised by himself, for moving the patient, a heavy and helpless woman, from the bed to the chair and back.

In answer to a question by Dr. J. J. PUTNAM as to the form of spinal sclerosis in this case, Dr. CUSHING said that the spinal cord had not yet been subjected to microscopical examination, but that the movements of the patient were not the abrupt incoördinate efforts of locomotor ataxia, and that the case was considered one of multiple sclerosis.

Dr. T. B. CURTIS remarked that Dr. Wm. Roberts, in his treatise on renal and urinary diseases, had devoted a paragraph to the subject of fatty matter in the urine, in which it was stated that several instances of a discharge of oil from the bladder had been recorded. One such case was reported by the late Mr. Turner, two others by Mettenheimer. In all these cases the patients were taking cod-liver oil. No explanation of this extraordinary phenomenon is offered. Roberts states, however, that dogs and cats, eating abundant fatty food, often pass an oily urine.

Dr. FORSTER briefly mentioned the case of a young girl whom he saw who passed oil in the urine in considerable quantity.

FEBRUARY 7, 1881. Dr. DWIGHT reported a case of recovery after a large dose of laudanum.

The patient, a middle-aged man, had taken two and one fourth ounces of laudanum eight hours before he was seen by Dr. Dwight. Shortly before taking the poison he had a light meal of bread and beer. For six of the eight hours since the ingestion of the laudanum he had slept quietly. Dr. Dwight found him slightly cyanotic, but able to tell his own story. In Dr. Dwight's presence he vomited quite profusely for the first time. The vomitus consisted of half-digested food reeking

¹ See page 242 of this number of JOURNAL.

with laudanum. Further vomiting was induced by ipecac and warm water, and finally coffee was administered. He made a good recovery. The reporter called the attention of the society to the long retention and non-absorption of the laudanum in a not overloaded stomach, which should encourage us to use emetics even long periods after the ingestion of poisons.

DR. ELLIS said that the presence of food in the stomach would retard the absorption of any drug.

DR. BUCKINGHAM thought the long non-absorption of food in this case would indicate that the stomach was disinclined to absorption of any kind.

DR. FORSTER read a paper upon Two Cases of Anomalous Gout. Both patients were drinking men, and both were similarly attacked by tonsillitis, accompanied by some fever. In one of the cases there was much œdema of the uvula and neighboring parts. These local symptoms yielded but slowly to topical applications, and were immediately followed by manifest gouty attacks in the small joints of the toes. This leading to the recognition of the nature of the affection colchicum was administered with speedy relief to the symptoms. Dr. Forster, in looking up the subject, had found tonsillitis mentioned as a rheumatic manifestation, but could nowhere find it ascribed to gout.

DR. LANGMAID said that he thought most practitioners would be ready to state their belief in the fact that tonsillar inflammation is a not infrequent gouty manifestation. Another symptom of gout which he has noticed and never seen mentioned is a lameness of the muscles of the pharynx. This will sometimes last for some time with but little redness of the fauces. He has been in the habit of using salicylic acid in these cases.

DR. T. B. CURTIS remarked that several authors had mentioned *cyanche tonsillaris* or *tonsillitis*, among the numerous disorders to which gouty subjects were specially predisposed. Certain inflammatory affections have been observed to occur with unusual frequency, sometimes repeatedly, in persons presenting the usual signs of the gouty or lithæmic habit. Such is the case, for instance, with lobar pneumonia, from which disease, Sir James Paget tells us, in his clinical lectures, that he has suffered seven times. This unusual susceptibility of his lungs he attributes to a rheumatic or gouty constitution. Chronic catarrh of the fauces is by general experience a very common complaint in gouty persons. Of course it is not to be understood that every case of tonsillitis or of pneumonia is to be considered as significant of lithæmia, but that these affections, when taken in conjunction with other concurrent evidence, or when recurring repeatedly in the same subject, testify in a certain measure to the existence of the constitutional state which we call gouty.

DR. ELLIS said that it would be interesting to know the comparative frequency of gout in England as compared with this country. He thought gout comparatively rare here, while these throat affections are common. From their very frequency you would expect them sometimes to coincide with gouty attacks without necessarily supposing any connection to exist between the two.

DR. CURTIS was reminded by Dr. Ellis's allusion to the differences of constitution or of morbid tendency observable in Englishmen and Americans of a remark made recently by Dr. Edes in his very interesting lectures on Bright's disease, which seemed to throw

some light upon the nature of these generally recognized differences. It is commonly agreed that *over-eating*, that is to say, the habitual consumption of more food, mainly nitrogenous, than the organism requires, or can, under the existing circumstances, properly disassimilate in the form of completely oxidized products, — namely, urea, carbonic acid, and water, — is the main cause of the gouty state, in which the system is kept constantly more or less charged, not to say poisoned, by arrears of imperfectly oxidized products of disassimilation. In order that this surplus of nitrogenous materials may accumulate and undergo imperfect combustion in the blood and tissues, it is obviously an indispensable condition that digestion and absorption should first take place on a sufficiently large scale to keep the system supplied with the necessary excess of nutriment; in other words, there must exist in such cases a considerable appetite and capacity for food, and a certain kind and degree of digestive power. But the habitual over-eating and under exercise which, under such eupeptic conditions keep the blood over-charged with nitrogenous materials, and thus engender the gouty state, may, under other circumstances, simply result in what Dr. Edes calls "the more obvious and perhaps safer dyspepsia of the *primæ viæ*," — safer in the same way that, in cases of poisoning, emesis is safer than absorption; safer because less damage, or, at any rate, a different kind of damage, is occasioned by an undigested meal than by the excess of nutriment which results from complete digestion and absorption. Now may it not be that, with the increased comfort and luxury attending on the present state of civilization, over-eating has become a common, almost universal cause of disease both in England and in America; in the former country, however, highly developed powers of digestion being, for some reason or other, the rule, and gouty derangements the result; while with us, on the contrary, pure dyspepsia without gout — "the more obvious and perhaps safer dyspepsia of the *primæ viæ*" — is the national disease?

DR. GARLAND said that his own case would militate against the idea that dyspepsia is a prophylactic to gout. He had gout in the toe come on after a long exhausting siege of dyspepsia with diarrhœa. At the present time a heavy meal is almost always followed by dyspepsia with simultaneous gout. He is not troubled with tonsillitis, and three members of his family of gouty tendencies are free from it.

DR. CURTIS remarked further upon the infrequency of true "ulcerated sore throat." The opinion has even been expressed by some specialists that such a condition occurred only as a result of syphilis. A great majority of the cases commonly spoken of, both in and out of the profession, as "ulcerated sore throat," and very many of the cases called "diphtheritic sore throat," to frequent recurrences of which some patients are said to be liable, and many cases unequivocally asserted to be diphtheria are simply cases of herpetic angina, — the *angine herpétique* of the French, the *angine couenneuse commune* of Bretonneau, Trousseau, and Gubler. This acute affection, which is apt to recur frequently in the same subject, is sudden in its onset, and often attended by much pain, distress, and fever. It is characterized in its earlier stage by a crop of herpetic vesicles which form upon the mucous membrane of the fauces; these soon coalesce and break, leaving a raw, desquamated surface, upon which a loose, soft, grayish false membrane is liable to be de-

Not uncommonly *herpes labialis* accompanies or follows the other symptoms, and is then diagnostic of their real nature. The disturbances attending herpes of the pharynx are often very severe, much more so than in incipient cases of diphtheria, where the onset is mostly gradual and insidious, with little pain, fever, or distress.

DR. LANGMAID said that he knew the appearances described, but had never been able to make them out as herpetic. He called attention to the frequency with which attacks of angina are to be traced to bad drainage.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

THE TREATMENT OF EXTRA-UTERINE GESTATION.

At a stated meeting of the society held February 28th, Prof. William T. Lusk read a paper on the above subject. In commencing, he alluded to the fact that extra-uterine pregnancy was a condition which existed much more frequently than was formerly supposed to be the case, and stated that for its present knowledge of the subject the profession was greatly indebted, first to the late Dr. John S. Parry, of Philadelphia, and, secondly, to Prof. T. G. Thomas. As cases of this kind were now known to be comparatively common, the question of treatment, therefore, assumed a high degree of importance.

The natural termination of tubal and interstitial pregnancy was by rupture of the sac, hemorrhage, peritonitis, and death; although there was a certain number of spontaneous recoveries on record, either through the mummification of the fetus or the formation of a fistulous tract through which it was gradually discharged in small portions. In ovarian and abdominal pregnancies the death of the fetus might take place either prematurely or at full term, and in the majority of cases it resulted in suppuration, which was almost sure to be followed by peritonitis and the death of the mother. Occasionally, however, the latter survived, and a fistulous opening was established into the vagina or rectum, or through the external abdominal walls, by means of which elimination took place. But this process of elimination was ordinarily a very slow one, and in the greater number of instances the patient required active interference on the part of the medical attendant, or else death would eventually ensue from blood-poisoning or exhaustion. Again, in a certain proportion of cases the fetus after its death became coated with a bony or earthy crust, and remained as a comparatively innocuous tumor during the rest of the woman's life. Its presence under such circumstances did not prevent the occurrence of pregnancy subsequently.

The treatment of extra-uterine gestation, Dr. Lusk continued, varied according to the stage of pregnancy. In cases of early gestation the indication was plainly to destroy the life of the fetus, and in order to accomplish this without injury to the mother a number of methods had been suggested and practiced. One of the most simple was the puncture of the sac, and this could usually be easily effected by means of a trocar introduced through the walls of the vagina or rectum. It was true that a number of recoveries were on record in cases where this plan was adopted, but the results, as a rule, were unfavorable. The second method mentioned

that of injecting poisonous solutions into the sac, by means of the hypodermic syringe. The first used was one fifth of a grain of sulphate of atropia in a small quantity of water; but Friedreich had substituted the fifth of a grain of morphia for this, and had reported two successful cases under its use.

The third method was that resorted to by Thomas, namely, the use of the galvano-cautery. One case barely escaped resulting fatally in his hands, however, and in the latest edition of his work on diseases of women (which contained a chapter on extra-uterine pregnancy) he recommended Paquelin's cautery. It was to be employed only after the pregnancy had given rise to symptoms of trouble. The fourth and last method considered was the use of the faradic current. It was to be kept up for from five to ten minutes through the seat of the product of conception, and repeated from time to time, if necessary, for one or two weeks, until the shrinkage of the tumor left no doubt that the passage of the current had produced the desired effect. Dr. Lusk then related in detail the history of a very interesting case in which he had called Dr. Thomas in consultation, and in which the faradic current had been employed with complete success. The use of the faradic current, in this connection, he continued, the profession owed to Dr. James G. Allen, of Philadelphia, who reported two cases successfully treated by it in 1872. This method, Dr. Lusk considered, offered a much better chance of recovery than any other, and one great advantage of it was that it was accompanied by no drawbacks. So far as he knew, it had now been resorted to in nine cases, and in every one of them the result had been successful. When it was remembered that in one hundred and fifty cases collected by Hume there were only seventeen recoveries, the advance that had been made could be better appreciated. The subsequent treatment was that for peritonitis.

The second class of cases was that in which gestation was in an advanced stage and the fetus was still living. Here symptoms of exhaustion finally came on, and the patient was in great danger. Laparotomy in such cases, Dr. Lusk thought, ought to enjoy the highest confidence of the surgeon, provided its performance did not increase the jeopardy of the mother. Parry had reported twenty cases of primary operations, with eight children and six mothers saved; but after a careful study of these cases he had found that five out of six of the maternal recoveries ought really to be stricken out. The great and unavoidable danger in such operations was the difficulty or impossibility of removing the placenta.

Finally, he considered the class of cases in which gestation was prolonged after the death of the fetus. Under these circumstances it was a well-established rule not to operate during the continuance of labor pains. The fetus might at length become converted into a hard, innocuous mass, as mentioned at the outset; but this was the exception, and not the rule. Most commonly it underwent maceration, and the patient sooner or later began to suffer from exhaustion and symptoms of septicæmia. In some cases a fistulous opening was formed into the vagina, into the rectum, through the abdominal walls, or even into the bladder. Under such circumstances the treatment consisted in the enlargement of the fistulous tract, and the extraction of the fetus piece-meal through it.

Secondary laparotomy was a justifiable operation, and out of thirty-three cases reported there had been

nineteen recoveries. Of the two great dangers of the primary operation, hemorrhage and septicæmia, the first was very greatly diminished by the death of the fœtus and the changes ensuing upon it, and the second could be avoided to a considerable extent by the judicious use of the antiseptic precautions now at the surgeon's command. When circumstances permitted, therefore, it was advisable to delay operative procedures until obliteration of the maternal vessels had taken place. Whenever the operation was demanded by the condition of the patient, however, antiseptic surgery offered a fair chance of success.

The paper being before the society for discussion, Dr. Jacobi remarked that he had had but one case of extra-uterine pregnancy in his own practice. This occurred some time ago, and he had not treated it by the method so highly recommended by Dr. Lusk, although he was happy to say that the result had been a favorable one. The patient was probably at the beginning of the third month of gestation, and he had punctured the sac through the vaginal walls. He had also made a second puncture two days afterward. Half a year later, when he examined the patient, he had found a hard substance to the left of the uterus which to the touch reminded him of cicatricial tissue in any other part. Even to this day, although it was seventeen years since the operation, the fundus of the uterus was drawn over to the left by means of the contraction that had resulted, while the cervix pointed decidedly toward the right. With his present knowledge of the subject, and especially after listening to the results mentioned by Dr. Lusk in his paper, he would undoubtedly employ the treatment by the faradic current if he were to meet with another similar case.

Dr. Rockwell stated that he had successfully employed electricity in the treatment of three cases. The first was that of Dr. McBurney, which had been alluded to by Dr. Lusk, and which, having been published in full in the *New York Medical Journal*, was well known to the profession at large. The correctness of the diagnosis had been disputed in some quarters, but he did not propose to discuss this point. The second case was that of Dr. Billington, also mentioned in the paper of the evening, and the third he had seen quite recently. Dr. Lusk had spoken particularly of the use of the faradic current, but it seemed to him that the galvanic current would prove the most efficient in destroying the fœtus. In Dr. McBurney's case this was employed, and two applications were made. Before it was resorted to Dr. Thomas, who was one of the consultants, asked him if he could kill the fœtus in this way without doing injury to the mother, and he replied that he thought he undoubtedly could. The result, as was well known, was entirely satisfactory. In Dr. Billington's case he had made but a single application of electricity, and did not know how many had been made subsequently. In the third case there had been but one application — of the galvanic current — altogether, and the recovery had been as successful as in the other instances. These three cases constituted all his experience in regard to this interesting subject, but they at all events went a considerable distance towards settling the point that the fœtus might be destroyed without injury or danger to the mother.

DR. BILLINGTON said that in his case a positive diagnosis was made by Dr. Thomas, whom he called

in consultation, and that he had made four applications after the first one by Dr. Rockwell. The first three times he employed fourteen or fifteen cells, but the last time he used the full strength of the battery, thirty-six cells.

DR. MUNDÉ had seen three cases of extra-uterine gestation altogether. The first was in the service of Scanzoni, and was fatal. It was a case of ventral pregnancy, and the patient went beyond full term. The second occurred in Braun's clinic. The pregnancy had originally been either interstitial or tubal, and the fœtus at length escaped into the abdominal cavity. The woman was in a very cachectic condition, and it was decided to wait till her death before operating for the purpose of saving the child's life. As soon as she expired laparotomy was performed, but the child, which weighed nine pounds, was asphyxiated. The third case occurred in his own practice, and the circumstances were peculiar, the fœtus escaping through the uterine canal, as in Dr. McBurney's case. Before he met with it he had been disposed to doubt the accuracy of the diagnosis in the latter, as he could not understand how the fœtus could pass through the undilated uterine canal. Now, however, he was quite willing to take back all that he had said upon this point, for the case in his own experience had completely convinced him that such a thing was quite possible. In this case he had sounded the uterus with the probe and found it empty, and yet twenty-four hours afterward he found the uterine cavity occupied by the fœtal mass, while the tumor which had previously existed above the uterus had entirely disappeared. In this instance bimanual examination was unusually easy, and there could be no doubt whatever of this latter fact.

It seemed to him that Dr. Rockwell was correct in his view that the galvanic was to be preferred to the faradic current in these cases. There were two reasons that occurred to him why the galvanic was preferable. First, the faradic current had the effect of causing a contraction of the muscular fibres of the tube, and, second, while the faradic current might kill the fœtus by the shock it produced, the galvanic had the additional advantage of decomposing the amniotic fluid.

In Dr. McBurney's case Dr. Emmet had made a suggestion, which he thought might prove of service in a certain proportion of instances. "Why not dilate the uterine cavity," said he, "and extract the fœtus in this way?" This might, perhaps, be a bold and difficult procedure, but, in the hands of an operator as skillful as Dr. Emmet, could no doubt be successfully accomplished in some cases of tubal or interstitial pregnancy. When rupture of the tube had taken place, he believed it to be quite justifiable to perform laparotomy, as proposed by Kiwisk, and, with all the resources of modern surgery now at one's command, he thought that the prospect of success would be as good as in many bad cases of ovariectomy.

In concluding the discussion, Dr. Lusk remarked that the galvanic current had been proposed in the treatment of extra-uterine pregnancy as early as 1857. At first its introduction in this field of surgery was hailed with great enthusiasm; but afterwards the plan was abandoned because the operators found that they did not obtain as good results from it as from simple puncture of the sac. It was after the use of the galvanic current had been given up that Dr. Allen resorted to the faradic current, and up to the present time (as

he had mentioned in the paper) nine cases had been reported in which it had been successfully employed without the occurrence of a single bad symptom. Or, leaving out Dr. McBurney's case, in which he had been under the impression that the faradic current had been used, until corrected by Dr. Roehrig, this evening, there would be eight successful cases on record.

PROPOSED LAW TO REGULATE THE SALE OF PATENT AND PROPRIETARY MEDICINES.

Dr. H. G. Piffard presented for the consideration of the society a bill which an effort was now being made to have passed by the legislature, and which he said combined some very objectionable features with some that were really excellent. It was in five sections. The first provided that all patent and proprietary medicines should have their exact composition printed upon the exterior of the bottle, box, or package in which they were sold; the second, that three commissioners, the chairman of whom should be the president of the county medical society, should have the power of examining all such medicines, and, if necessary, the process of their manufacture, when, if they found nothing injurious in their ingredients, they should be required to furnish a certificate to that effect; the third provided that such commissioners should receive pay at the rate of ten dollars a day for all time actually spent in the performance of their duties; the fourth provided that certain penalties should be inflicted for infringements of the law; and the fifth, that the act should go into effect immediately.

The first and fourth sections, Dr. Piffard said, were altogether unobjectionable and their enforcement, he believed, would be of great service to the profession and the community at large; but the second and third were unnecessary and were open to very serious objections. If the second section were passed by the legislature, all patent medicines that were examined and favorably reported upon by the commissioners would be advertised and offered for sale as endorsed by the medical profession. In regard to the third section he remarked that a work of this kind would take all the time of the commissioners, and that probably no one occupying the position of president of the county medical society would be willing to give up his practice for ten dollars a day. Moreover, as the bill was now constructed, the office of commissioner was apparently for life; no definite time being specified for its continuance. On motion of Dr. Piffard, it was decided that after sections two and three had been stricken out, and one or two slight alterations made in the others, the president and secretary should be authorized to endorse the bill on behalf of the society.

Recent Literature.

Proceedings of the Association of Medical Officers of American Institutions for Idiotic and Feeble-minded Persons. Session: Barre, Mass., June, 1880.

The subject of the care of the feeble-minded, though to the philosopher and the physiologist it presents problems of the highest interest, has not yet made itself attractive to physicians at large, even so much as that of the care of the insane. It is, therefore, all the more important that we should take advantage of these yearly meetings of superintendents to take notice of the work

that is being done in this direction and express our recognition of its value.

The first fact, and certainly the most important one, that strikes us in looking over this pamphlet descriptive of the fifth annual session of the Association, is that this unfortunate class have many warm friends among us and are being cared for as well as circumstances permit. The next is that the strictly scientific work done by the Association is of but trifling amount. There is no use in dwelling on this too obvious fact, nor of spending too much time in deploring it. The character of men's work is usually determined by circumstances, and so it is in this case.

The only urgent demands that have hitherto been made are: first, that our idiots should be well looked after and kindly treated; second, that they should be taught to become decent members of society; and we have only to congratulate ourselves that these demands are being so well met. The rest will come in good time, after the need of better scientific training is recognized for this department, as it is coming for the department of insanity, and in proportion as opportunities are afforded to superintendents and assistants for its accomplishment.

The first of the four communications is from the late Dr. E. Seguin on the Training of the Idiotic Eye and Hand, and through them, of course, the mind. Though couched in the peculiar, half French, half mystic language of the writer, it is of interest as pointing the way towards a method by which laurels may undoubtedly be reaped and much good done, by any one who has the patience and skill to pursue it.

The second is an able statement by Dr. H. B. Wilbur, of the opinion, which but for his quotations we should not have supposed needed demonstration, that in idiocy the instinctive faculties, so far from being predominant, as has been claimed by Carpenter, Maudsley, and others, suffer with the intellectual faculties, and for similar reasons.

The third, by Dr. George Brown, of Barre, denominated Occult Epilepsy, is a rather crude pathological study.

The fourth, on the etiology of idiocy, by Dr. J. N. Kerlin, consists of a table of one hundred cases grouped in a manner to bring out a number of important facts in the causation of this state. The entire investigation aims at embracing one thousand cases, and will no doubt prove of great interest. No analysis is here attempted, and we waive further notice of it till the whole work shall be complete.

The Microcosm and other Poems. By ABRAHAM COLES, M. D., LL. D. New York: D. Appleton & Co. 1881.

The microcosm, the leading poem of this collection, was first published in 1866, in connection with an address delivered at the same time by the author, as president, before the Medical Society of New Jersey, at its centennial anniversary. It is, as the author tells us, an Essay on Man, in verse, whose scope, unlike that of Pope's, is physiological rather than ethical. The other poems were written for the most part many years ago.

The author makes no apology for their religious character; he is glad he has not outgrown Christianity, and prefers a humble faith to a conceited agnosticism. Dr. Coles is the author of *Dies Ire*, in thirteen ver-

sions. Whittier said of the *Microcosm*, when first published: "The idea of the poem is novel and daring, but it is marked out with great skill and delicacy." The volume is a very handsome specimen of the publisher's work, and contains five artetype illustrations.

Hand-Book for Coroners, containing a Digest of all the Laws in the Thirty-eight States of the Union, together with a Historical Résumé. A Guide to the Physician in Post-Mortem Examinations, and Valuable Matter never before collated. By JOHN G. LEE, M. D., Coroner's Physician of the City and County of Philadelphia. Philadelphia: Published by William Brotherhead. 1881. Pp. 228.

The almost simultaneous agitation in the direction of a change in the inquest laws of the States of New York, Louisiana, North Carolina, Indiana, and other States of the Union, would appear to show that the recent action of the Old Bay State has awakened a wide-spread interest in the subject. If it is desirable to perpetuate in the United States that old relic of Saxon barbarism, the coroner system, the Coroner's Hand-Book has appeared in good season. Let us hope that it will be used for a better purpose. Part I. of this book is worthy the perusal of the medical examiner or of the medical coroner. The first chapter constitutes an excellent contribution to the history of forensic medicine, being a compilation of the principal facts relating to the history of the primary investigation of crimes from the earlier centuries of English history down to the present time.

For the benefit of such State governments as have not yet determined to abolish the entire system the following passages may be commended as an entering wedge: "A lawyer, or a private individual, if handed a watch which had suddenly ceased to go, either from a fall or from any unknown cause, would not be expected to state the cause of its stoppage. Yet this is what the *non-medical* coroner is expected to do with the thousand times more intricate piece of machinery, the human body." "We consider our position impregnable, when in behalf of the community at large and in the interest of public safety we urge that the office of coroner, in this country as well as in England, should be filled by an intelligent and thoroughly educated medical man, of inflexible principle and irreproachable morals." The author, whose volume is dated 1881, scarcely recognizes the medical examiner system of Massachusetts. His arguments favor the continuance of the ancient coroner system, with this single advance, that the office should be filled exclusively by medical men. The medical examiner law of this commonwealth is dismissed with a notice of four lines in length on page 30, and an allusion of similar length on page 171. This is very like Hamlet with Hamlet left out.

On page 54 the author states: "In England and the United States forensic medicine is in its infancy." True enough, and what has kept the nursing so long in its cradle but this same old coroner system, which the author seeks to perpetuate, with its useless juries, whose verdicts have so often brought ridicule upon the system and hindered the progress of thorough medical investigation? In those countries where forensic medicine has made the most rapid strides—Germany, France, and Italy—coroners and their juries are unknown, and it is chiefly upon the laws of those conti-

nental nations that the Massachusetts medical examiner system has been modeled and adapted to the wants of a New England people.

Chapter II. is devoted to the *Coroner's Physician*, and contains many suggestions which are available for the medical examiner or medical coroner. Especially commendable are the remarks on expert testimony, the conduct of the medical witness, the details of autopsies, and suggestions in regard to the exhumation of bodies.

Chapter III., entitled *The Aspects and Surroundings of Death*, contains valuable information relating to the diagnosis of wounds inflicted before and after death. The signs of death are also treated somewhat after the style of Casper, though more briefly. Cadaveric rigidity and cadaveric spasm are also fully treated, with illustrations from Brinton,¹ Rossbach, Kiessmaul, and others. Post-mortem staining and ecchymoses are also briefly treated. The chapter closes with some very useful directions as to the preservation of blood-stains, and also the solidification of foot-prints in soil and in snow.²

No better argument against the coroner system could be found than the following statement on page 107: "Unfortunately, in this case permission could not be obtained to make an autopsy, the privilege of making the same being waived by the coroner."

Part II. contains a digest of the existing inquest laws in all the States of the Union. A perusal of these ancient statutes reveals the fact that while the old coroner system is at present employed in nearly every State, the coroner laws of all the States differ from each other in many points, prominent among which are the modes of election or appointment, the number of men required for a jury, the fees of officers, of juriesmen, etc., etc.

The physician who performs an autopsy at the direction of a coroner in Minnesota receives the sum of six dollars, while in Mississippi he receives for a like service fifty dollars, and in a case of exhumation one hundred dollars. In Indiana the coroner's jury has been abolished. In New York any citizen may demand that a jury shall be summoned, and in the same State there is a law forbidding the disturbance or removal of any body which has suffered a violent death. In South Carolina every fatal case of rattlesnake bite requires the services of a coroner. In Connecticut and in Vermont the office of coroner does not exist, but is supplied by a justice of the peace. The same custom has also a temporary existence in other States in districts where no coroner has been appointed. It is a curious fact that one of the old English usages relating to the coroner's office should have been incorporated into the laws of many of the States,—that of serving occasionally in the vicarious capacity of sheriff. Fortunately, our new medical examiner law of 1877 was shorn of this useless incumbrance.

It is presumed that the author has intended to cite correctly the laws concerning inquests now in force in the various States, but we find on page 170 a poor guarantee of his accuracy. Under Massachusetts he gives us, not chapter 200 of the Acts of 1877, creating the medical examiner and abolishing the coroner more than three years before this book was printed, but an imperfect abstract of some of the provisions of law under which the now extinct race of coroners

¹ American Journal of the Medical Sciences, January, 1870.

² Hugoulin. Annales d'Hygiène Publique, vol. xlv., p. 429.

acted before July, 1877. The only Massachusetts law of recent date relating to inquests which he has stumbled upon is a verbal amendment to the general railroad law requiring corporations to notify "medical examiners" instead of "coroners" concerning casualties on their lines; and this citation is made in such a way as to convey no notion whatever of the import of the act cited. Such an omission, we are sorry to say, tends to discredit the trustworthiness of the author's other citations.

A dozen pages of humorous anecdotes close the volume, and form not the least of the numerous arguments against the coroner's jury.

The author has had a large and varied experience in medico-legal autopsies. A volume comprising a compilation of his medico-legal work, with a selection of such cases for publication as are of special medico-legal interest, would form an important contribution to the literature of forensic medicine. S. W. A.

Syphilis and Marriage. Lectures delivered at the St. Louis Hospital, Paris. By ALFRED FOURNIER, professeur, etc., médecin, etc., membre de l'Académie, etc. Translated by P. ALBERT MORROW, M. D., etc. New York: D. Appleton and Co., 1, 3, and 5 Bond Street. 1881. Pp. 251.

The thanks of the medical profession and of the community are due to Dr. Morrow for his excellent translation of this invaluable book, which emanates from perhaps the first syphilologist of the world, and treats, in a masterly way, of one of the very most important subjects in medicine, one hitherto, moreover, almost entirely ignored. In this volume the relations of syphilis with marriage have been exhaustively studied, and the practical questions, medical and social, growing out of it, been discussed in a thoroughly systematic and comprehensive manner. Special prominence is given to the moral obligation imposed upon the physician as regards public prophylaxis, and rules are formulated to guide his conduct in dealing with the various complex and difficult problems which may arise. The book supplies a want long recognized in medical literature, and is based upon a very extended experience in the special hospitals for syphilis of Paris, which have furnished the author with a rich and rare store of clinical cases, utilized by him with great discrimination, originality, and clinical judgment. It exhibits a profound knowledge of its subject under all relations, united with marked skill and tact in treating the delicate social questions necessarily involved in such a line of investigation. The subject naturally divides itself as follows: (1.) What conditions ought a syphilitic person to fulfill medically to justify us in permitting him to marry? Or, conversely, under what conditions will it be our duty to defer or even to absolutely interdict marriage? And (2), when syphilis has been introduced into the conjugal bed by the consummation of marriage, what medical indications are to be then fulfilled in order to lessen or avert the dangers of such a situation? In other words, what is, under such circumstances, the proper rôle of the physician either before or after marriage? To the former division of the subject Fournier devotes eleven chapters, to the latter five. The eleven chapters treat of preliminary questions; direct contagion; syphilis by conception; paternal heredity; mixed heredity; maternal heredity;

personal dangers of the husband; conditions of admissibility to marriage; prolonged period of immunity; sufficient specific treatment; conclusions. Part II. considers the problems of,—husband syphilitic and wife healthy; husband syphilitic, wife healthy but encephalic; husband syphilitic and wife recently contaminated; husband syphilitic, wife syphilitic and encephalic; dangers to society, social prophylaxis. Some very interesting notes and illustrative cases are appended, for example, eighty-seven observations of syphilitic husbands who never affected their wives while begetting one hundred and fifty-six absolutely healthy children; case of syphilis causing seven abortions; statistics of hereditary influence of maternal syphilis; cases of syphilis contracted before but first appearing after marriage; five cases of syphilis, due to the husband's syphilis, with death of a strange nursing; father and child infected, mother apparently not, but presenting, six years later, an accident of tertiary syphilis (case); inaptitude for life as a hereditary consequence of paternal syphilis. The entire volume is full of information, mnemonically condensed into axiomatic "points." It is a book to buy, to keep, to read, to profit by, and to lend to others. E. W.

Food for the Invalid. By J. MILNER FOTHERGILL, M. D., Edinburgh, and HORATIO C. WOOD, M. D. New York: Macmillan & Co. 1880.

The introduction to this little book is an excellent epitome of the present application of physiological knowledge to the kitchen, and many of our readers will be pleased to catch at a moment's glance certain hints which would require the study of several hours devoted to modern works on the physiology of digestion. The "recipes" or receipts for cooking are too hurriedly put together to form a useful cookery-book. We should hardly be satisfied with the method proposed for making "beef juice for the sick": "Cut one pound of beef in small pieces, put it into a bottle, and cork it up," etc. Any one who has had a juicy piece of beef cooked slowly for ten minutes, scored and squeezed by one of the modern iron beef squeezers, would not relish the insipid liquid prepared by Dr. Fothergill's process. Most of the other receipts are valuable for the sick-room.

— Small-pox is still raging in Chicago. The number of hæmorrhagic cases is large, forming a considerable proportion of all the cases. The department of health is having a hard time to ferret out and find all the cases and take care of them. The disposition to hide cases from the department, and even from the profession, seems to be growing. Several cases have been discovered only after the death of the patient, and hence after all possible opportunity has existed for spreading the disease.

The obstruction is owing to the prejudice against the small-pox hospital and against being forcibly taken there. The prospect now seems good for the appointment of a medical man to take charge of and live at the hospital. A small appropriation for his salary is likely to be appropriated by the city council. This is a step in the right direction, and if the choice falls upon a good man the institution may be conducted hereafter without offense to the public.

Medical and Surgical Journal.

THURSDAY, MARCH 17, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE PROPOSED PHARMACEUTICAL LAW FOR MASSACHUSETTS.

A LETTER on another page of this number of the JOURNAL draws attention to a proposed law for the regulation of the practice of pharmacy. The principal features of the bill, which was brought before the legislature under the approval of the Essex County Druggists' Association, are as follows:—

Section 1 provides for the appointment by the Governor, with the consent of the council, of three men of long experience in the business of retailing drugs and chemicals and compounding physicians' prescriptions, to be Commissioners of Pharmacy, to hold office for one, two, and three years respectively; thereafter one commissioner to be appointed annually to hold office for three years.

Their duties shall be to examine all who may apply, and if qualified to give them certificates which shall entitle them to carry on the business of pharmacy in this commonwealth.

Section 2 provides for the registration without examination of all persons now actually doing business as pharmacists, provided they apply for registration within ninety days, and for the keeping a registry, to be always open for inspection, in the office of the Secretary of the Commonwealth.

Section 3 provides for a penalty of not less than one hundred nor more than five hundred dollars for engaging in the business of selling drugs and compounding physicians' prescriptions without certificate.

The act further provides for fees of five dollars for examination and of three dollars for the registration of those already engaged in the business. The sale of proprietary and domestic remedies is simply left without interference, except that domestic remedies shall be marked with the label of a registered pharmacist, and the dose given thereon. The commissioners are also charged with the duty of prosecuting violations of the act. Fines are to be paid half to the informant, half to the Commonwealth.

The absence of any *ex post facto* regulation of existing affairs ought to commend the bill to the general public; whether the public is yet ready to surrender its inalienable right of each individual citizen to sell drugs in the future, if at any time he chooses to exercise that right, without showing his fitness for the business, remains to be seen. The bill has already excited much opposition and has been the victim of great misrepresentation. That the public would be

greatly benefited by limiting the business to those able to discriminate between good and worthless drugs there can be no question. One of the chief arguments against the bill is based on the small number of fatal accidents that are reported from druggists' mistakes. The immense number of worthless drugs sold the public cannot appreciate, nor do physicians themselves seem to be fully aware of the vast number of inert prescriptions furnished. Much of the skepticism in regard to the action of drugs may be due to this very cause. The present condition of the drug business is compelling many physicians to carry about with them a certain number of drugs, and obliges them to discriminate between certain apothecaries whom they know to be qualified and certain others of whose qualifications they are ignorant.

The National Pharmaceutical Association is trying to bring about the regulation of the trade throughout the union, and, as our correspondent shows, has succeeded in introducing laws more or less valuable in several States. The working of the Rhode Island law is interesting in one particular. It has led to the establishment of a class for the study of pharmacy in the polytechnic school attached to the public evening schools in the city of Providence.

The medical profession will fully approve of the object of the proposed law. The agitation in regard to it will have at least one good effect. It will familiarize the community with the idea that special fitness is necessary for certain positions connected even remotely with the public health, and may also assist in teaching the public that pretensions to special knowledge are by no means a warrant of the actual possession of such knowledge.

THE COMPUTATION OF DEATH-RATES AS ILLUSTRATED BY BALTIMORE.

As our readers are aware, weekly mortality tables made up from the local returns of various cities throughout the country are published in the *Bulletin of the National Board of Health* and in the JOURNAL. The table of the *Bulletin* includes all the cities in the United States in which burial permits are required, that of the JOURNAL includes only a certain number of the largest cities outside and the cities and towns within Massachusetts. The *Bulletin's* tables are made up from returns sent by local health officials or registrars to the national board; the JOURNAL's tables from similar returns sent to the Massachusetts Board of Health. In the *Bulletin* the death-rates per thousand of the individual cities is given; in the JOURNAL this has not been done, except in a general way for the total population of the cities and towns of Massachusetts. We have been asked at times why we do not give the death-rate, by readers who would like to be able at a glance to determine the relative sanitary condition of the cities in different parts of the country.

The reason has been, hitherto, that these death-rates have been utterly valueless for a large number of the

principal cities, except, possibly, for comparing the mortality in the same place from week to week. Before the completion of the last census the death-rates were made up upon the basis of estimated populations. The diverse methods and degrees of care which prevail in different localities in the returns and registration of vital and mortality statistics make their absolute or comparative value sufficiently uncertain, but when to this was added the outrageous inflations of estimated population for purposes of local self-glorification the value of death-rates was not worth their calculation. This may be seen by comparing the estimated populations of some of the chief cities prior to the publication of the census with those resulting from the census: Philadelphia estimated 901,380, census 846,984; St. Louis estimated 500,000, census 350,522; Baltimore estimated 393,796, census 332,190; Cincinnati estimated 280,000, census 255,708. Prior to the census, if any remonstrance was made at the improbability of the accuracy of these swollen populations of competing cities, accompanied by a proposal to calculate death-rates upon a more reasonable basis, the answer from the local officials was, if anything of the kind is attempted no more returns will be sent.

It was supposed that this source of inaccuracy might, for a time at least, be escaped after the publication of the results of the late census, but Baltimore, as represented by her health commissioner, and the secretary of her health department, takes the earliest opportunity to correct any such delusion. She is not going to quietly submit to the decapitation of 60,000 of her population at one stroke by a bungling census-taker. Nor will she allow any unauthorized person, as her secretary takes pains to assure the public in a late number of the *Sanitary Engineer*, such as the secretary of the National Board of Health for example, to lay sacrilegious hands upon the sum total of her citizens. If the city cannot have a favorable report upon her hygienic condition from sanitary inspectors destitute of the fitness conferred by local pride, she shall at least have a favorable death-rate of her own in spite of it all. The secretary of the Baltimore Health Department is, however, a very conscientious person; he is, as he states in the letter from which we quote, "equally opposed to the alteration of his figures by unauthorized parties, or to the changing of them even by himself until fully convinced and satisfied that they are not correct." He professes to entertain the highest opinion of, and the utmost confidence in, the able superintendent of the national census, and that of course affords something to work on, otherwise we should say there was but little chance of convincing a person of error who arrives at his statistical conclusions by the peculiar method set forth in the following extracts from the letter to the *Sanitary Engineer*:—

The *Sun's* local states that "Mr. Carter makes up his report upon a basis of an estimated population of 393,796, which he claims the city has, in accordance with a calculation made with reference to the number of houses in the city."

This is only a partial statement of my basis of calculation. The secretary of the National Board of Health requested me to make my estimate as follows: whole population, 332,190; white, 278,487; colored, 53,703, which he stated was "official, as fur-

nished by the census department." This request, after consultation with the commissioner of health, I respectfully declined to comply with, as our estimate is: whole population, 393,796; white, 338,384; colored, 55,412; and we are satisfied that these figures are much nearer the correct population of Baltimore than those furnished by the national board. I have the very highest opinion of, and the utmost confidence in, General Walker, the able superintendent of the census, and am sure that his earnest desire is to have the census absolutely correct; but as far as the census of this city is concerned, I am fully convinced that it was incorrectly taken, as hundreds of citizens can testify to the incomplete character of the work done by the census agents.

It is a curious coincidence that our estimate of the colored population (our estimate, 55,412; official figures, 53,703) should so nearly approximate the figures of the census department, and our estimate of the white (our estimate, 338,384; official figures, 278,487) so widely differ from the official count. There are 80,000 registered legal voters in Baltimore; five inhabitants to a legal voter is a fair and reasonable allowance, which would make the population 400,000. The census taken by the police, for our school board, of children between the ages of six and twenty-one years, gave 86,961. This would be a fair estimate of one fifth of our population, making the same 434,805. Wood's "City Directory"—than which none more perfect or carefully compiled can be found in this country—gives, after deducting all firms, companies, and institutions, 84,596 white, and 13,853 colored, names. It is perfectly fair and reasonable to assume four inhabitants to each name, which would give our present estimate, 393,796.

Again, there are 90,000 houses in Baltimore. Deduct 10,000 for manufacturing establishments, warehouses, stores, and unoccupied dwellings, and estimating five inhabitants to each house (a very low estimate) our population would be 400,000. I am, therefore, fully satisfied that without any "statistical manipulation," or any attempt "to so cook the figures as to delude the citizens," the census of Baltimore, if correctly taken, would give her a population of fully 400,000.

As Hamlet puts it, when discussing with Luertes the mortality of Ophelia, we could accompany the secretary "upon this theme until our eyelids will no longer wag;" for example, again, there are in Baltimore one thousand streets; deduct two hundred streets occupied by stores, warehouses, etc., and allowing five hundred inhabitants—clearly a very moderate number—to each of the remaining eight hundred streets and we easily have a total population of four hundred thousand souls; etc., etc., *ad infinitum*.

When one consults the mortality tables published by the English or German government bureaus he finds death-rates whose relative and absolute value can be estimated and relied on, but the death-rates of our cities as given by the National Board of Health are of but very little value to any one unless based on the census returns. If each civic sanitary official is to have his own pet methods of computing population, and each city a numerical aspiration to be attained at all hazards, the farce of computing death-rates may as well be given up altogether, and the clerk of the local board may more profitably devote himself to composing paragraphs for the local press after this fashion: "Healthy Smithville! There is no doubt that if the death-rate of Smithville were properly calculated during the past three months it would prove to average 11.3. In London, Paris, and Berlin, during the same period, it has been 20, 23, and 25, respectively; this proves the advantages which Smithville enjoys over those other great cities, and is another indication that it will soon surpass them in wealth and population."

The intelligently ambitious city first increases the population to lower the death-rate, and then increases it still further because the death-rate is low.

MEDICAL NOTES.

NEW YORK.

— There is an effort being made at present by the State Charities Aid Association to get a bill passed by the legislature which will confer upon the officers of the Association the power to visit, inspect, and examine any of the State charitable institutions, county poor-houses, town poor-houses, and city almshouses within the State; but inasmuch as the State Board of Charities, which is already thus empowered, is a very efficient organization, the adoption of such a measure is not regarded with favor by those best qualified to form an opinion in such matters. There seems to be no reason whatever for establishing two corporations in the State, both of which have practically the same objects in view, when one of them can accomplish the work desired, and it is to be feared that in case the bill should pass, the recommendations made by the State Board and the Aid Association in regard to legislation deemed necessary might sometimes prove conflicting, so that a constant dispute might perhaps be kept up between the two bodies.

— A sub-committee of the State Board of Health, consisting of Mr. Erastus Brooks, Dr. J. S. Delavan, and Dr. Elisha Harris, is at present engaged in making an investigation of the effluvium nuisances in the vicinity of Hunter's Point and New York. The committee was appointed at a meeting of the State Board of Health, February 9th, at the request of the New York Sanitary Reform Association, and at its first session Mr. Pellet, of the latter society, presented a petition signed by many of the most influential citizens of New York asking for action on the part of the State board, since the seat of the nuisances was without the city limits, and therefore beyond the control of the local board of health. Dr. Elisha Harris pointed out the location of the phosphate manufactories, chemical works, oil refineries, and other sources of offensive odors in East Brooklyn, Greenpoint, and Long Island City; and a number of letters from physicians in regard to the injurious effects of the latter were read. Thus, Dr. C. R. Agnew wrote; "They both create and increase disease from causing windows and other ventilators to be closed, and so depressing the general tone of health and increasing liability to disease; also making people who are deficient in self-control — the majority of the inhabitants of the district — fret and worry, and making them apprehensive of disease. I consider a bad stench a source of disease, because it in many ways vexes the nervous system of sensitive people."

PHILADELPHIA.

— The most recent interesting event was the inauguration of Dr. William Pepper as Provost of the University of Pennsylvania. The exercises were held on Washington's birthday, at the Academy of Music, a large and brilliant audience witnessing the ceremony. A number of distinguished invited guests, among whom was President Eliot of Harvard, occupied seats upon the stage. The exercises were most

interesting and impressive. Governor Hoyt, of Pennsylvania, who is ex-officio a member of the Board of Trustees, made an opening address in which he referred to the history and progress of the University of Pennsylvania, and considered the requirements of the position to which Dr. Pepper had been called, and presented the new incumbent with the keys as the insignia of his office. An address of welcome to the new Provost was then delivered by the Vice-Provost, Rev. Dr. Krauth, on behalf of the Faculties, and concluded with a fitting tribute to the late Provost, Dr. Charles J. Stillé, to whose tireless energy and devotion the institution owes mainly its present position. At the conclusion of these remarks Dr. Pepper made a temperate and able address containing much of general interest and of more than a local application.

The new Provost conferred the degree of LL. D. upon President Garfield.

WASHINGTON.

The National Board of Health has had the funds at its command materially diminished by a clause in the Civil Appropriation Bill as discussed and passed February 23d. This clause reads as follows: "National Board of Health: For salaries and expenses of the National Board of Health, to carry out the purposes of the various acts creating the National Board of Health, \$75,000 or so much thereof as is necessary, *provided* that \$25,000 of the appropriation made by act of June 2, 1879, entitled An Act to Prevent the Introduction of Contagious or Infectious Diseases into the United States, shall be applied to the same purposes, and no more money shall be expended for the above purposes out of any appropriations heretofore made or by virtue of any previous law."

Mr. King, of Louisiana, in discussing this action, stated there was a balance of \$180,000 left out of the first appropriation, and also that the cost of one epidemic alone of yellow fever to the city of New Orleans was not less than \$12,000,000. Mr. Blount, of Georgia, who represented the committee on appropriations in the discussion, stated that the act creating the board of health was not to continue in force for longer than four years, yet a system had been adopted of building expensive and permanent quarantine stations, and contracts were made looking to the permanency of the board. Further that the treasury department had decided that the board could use the whole of its fund in a single year, therefore Congress now decides specifically what moneys might be used during the current fiscal year. Mr. Young, of Tennessee, considered Mr. Blount as not having the slightest information on the question, being without knowledge of the items and estimates submitted by the board. He then referred to these items and estimates as given by the board in asking for \$203,000 in addition to the unexpended appropriation remaining on hand, to be used in guarding the inlets of our southern coast and keeping up the quarantine stations, and compared the appropriation in the same bill of six or seven hundred thousand dollars for the Life

Saving Service, whose last report showed some ninety lives as saved, with this, referring to the loss in 1878 of some thirty thousand lives from the pestilence in the Mississippi Valley.

Mr. Goode, of Virginia, commended the board as showing no disposition to be wasteful or extravagant, the total appropriation being \$625,000, out of which but \$364,000 have been expended. He then referred to the advantages accruing from a quarantine station at Hampton Roads as protecting Richmond, Alexandria, Fredericksburgh, Baltimore, and Washington.

CHICAGO.

—The annual commencement of Rush Medical College was held February 22d. The number of ordinary graduates was 172. Two honorary degrees were conferred.—on Dr. Allport, the noted dentist, and on Dr. S. D. Jacobson, of the Cook County Hospital staff.

The attendance at the college during the college year just closed was 505 students. The secretary's report showed that the proportion of students who had received an academic education before entering the college was steadily increasing. During the past winter session there had been delivered 700 didactic lectures and 1080 clinical lectures; during the previous spring session the number of didactic lectures had been 400, and of the clinical lectures 256.

The doctorate address was delivered by the president of the faculty, Dr. J. Adams Allen. It was largely devoted to a review of the past history of the college, and showed plainly that the institution has since its establishment, forty years ago, made a large advance in the amount and character of the instruction given annually to its classes and in the requirements for a degree. The opportunities of acquiring a thorough medical education at this college now were shown to be many times as great as they were at the beginning, and in nothing was the change more apparent than in the amount and character of clinical instruction offered.

In the evening the faculty of the college entertained the alumni, old and young, at a banquet at the Tremont House, where there was the usual feasting and toasts.

—The epidemic of gastro-intestinal catarrh (called by the newspapers winter cholera) has not entirely ceased. The enemies of good water have about ceased attributing the cases to the drinking of our hydrant water, since it is found that many cases have occurred in rural villages in various parts of the Northwest. This fact, too, makes it likely that we cannot in any great degree charge the epidemic to our bad sewerage. Indeed, our sewerage is as good as it has been at any time, and sewer gas has not this winter been any more prevalent in the houses of the people than formerly. This whole subject has been extensively discussed in the daily press of late, and it is leading to one very good result, namely, to impress people that to construct a house with water-closets and sewers within its walls, and without offense and without harm to the

atmosphere, is no easy thing, and that if people living in such houses would conserve the healthfulness of their habitations they must occasionally pay some slight attention to the condition of the sewerage thereof.

—The question of ventilating the main sewers by perforated covers for the street openings has again been brought to the attention of the public by the recommendation of the commissioner of health that a sufficient appropriation be made for this object to give the measure a fair trial and make it a success. Last year the measure was undertaken but the appropriation was insufficient, and so in most places it was only half carried out; as a consequence, in quarters where the ventilators were far apart, the emanations from each at times gave to the passer-by an unpleasant odor. This never in any case amounted to a real inconvenience to any one, yet it was enough to frighten some into the belief that they were being poisoned with sewer gas, and that therefore the ventilators ought to be closed. Even some intelligent members of the profession have become possessed of this delusion. Let us hope that all the sewers may be ventilated into the middle of the streets instead of into the houses. Chicago has breezes enough to dilute sufficiently any quantity of sewer gas thus delivered into the open air; she has no better facilities than other cities for taking care of it when set free in her houses.

—Another new measure the commissioner has asked an appropriation for, with strong probability of success, is to place a resident physician in charge of the small-pox hospital. Heretofore all the patients at that institution have been left in charge of the nurses and steward during the absence of the city physician, who has never made more than one hurried visit each day; frequently his visits are only once in two days. When we consider that sometimes as many as forty patients are in the hospital at once, many of them desperately sick, it is a wonder the public has not before made complaint of this real neglect of the sick.

—The Woman's Hospital Medical College held its commencement on March 1st. Seventeen ladies received the degree of doctor of medicine. This is by far the largest class ever graduated from this institution. The college is to be commended for the thorough work it is doing. Its graduating classes have uniformly passed final examinations as creditable as those in any of the colleges for men. All parties in and out of the profession are agreed that, whether it is a good thing or not for women to study medicine, if they do study and practice they should be thorough in their preparation for the work.

—The epidemic of small-pox continues and the health department has issued a proclamation that all people who have not been successfully vaccinated within seven years must be vaccinated forthwith. Although several people will probably fail to obey this requirement, it nevertheless will have a good effect, as we are told this gives the warrant of law to the health inspectors (physicians) in compelling people in the near neighborhood of cases of variola to be vaccinated, which they did not before have authority to do.

PHARMACEUTICAL NOTES.

—The *Druggist*, of Chicago, reports a serious blunder through which two children of that city recently lost their lives. Muriate of morphia was given them for muriate of quinia. The mistake was charged to the attending physician, who laid it upon the apothecary, and he fell back on the manufacturing chemist with the statement that the drug was dispensed from a bottle bearing the manufacturer's label, and marked plainly muriate of quinia. — *Louisville Medical News*.

Miscellany.

THE PROPOSED PHARMACY LAW.

MR. EDITOR, — Allow me to call your attention to the pharmacy law now before the joint committee on public health in the legislature, and give a few reasons for its passage.

For several years past much interest has been manifested by many in the drug trade arising from the need of a law regulating, as far as possible, the *education* of those engaged in the preparation and sale of medicines. The large increase of retail drug stores, set up many times by those who have not passed through the requisite course of experience, under an impression that the business is more lucrative than any other, or used as a cloak for other business not as respectable, has many times brought the legitimate business into disrepute; and the alarming increase of accidents caused in part by the ignorance and carelessness of apothecaries has led the *public* to feel that a law should be passed for their prevention. In view of these two conditions, it is believed that some law could be framed which, while it would protect the public, at the same time would be of benefit to the apothecary by elevating the status of his profession.

The American Pharmaceutical Association, composed of 1200 of the best pharmacists from Maine to California, and from Canada to Panama, have discussed the matter of pharmacy laws, and have put on record their opinion of the same. The origin of the Association was the need of a law to prevent the importation of spurious drugs; as a natural consequence to this was the question of home adulterations and the education of pharmacists. In all these matters they have been opposed by those who now oppose the passage of a pharmacy law.

The Association has corresponded with the governors of all the States, has published a valuable amount of information in their Proceedings, and through their influence have induced twenty of the States to pass pharmacy laws; and we have evidence from the States of New Hampshire and Rhode Island that they have been productive of good.

The opponents of the law claim that as there are not a large number of fatal cases caused by the mistakes of apothecaries, a law is not needed. This is not the point at all, and only serves to cover over the real cause of opposition. It is the unheard-of and unknown mistakes of apothecaries caused by *ignorance*, *carelessness*, and *cupidity* that are the most dangerous. For if a physician is prescribing a powerful remedy to a very sick patient, and expects a certain effect from a small dose, which he does not get if the article prescribed by him and put up by the apothecary is not

up to the standard, what reason can be given why the apothecary is not responsible for the failure.

It is the custom of many apothecaries, particularly those who live at a distance from the great centres of trade, in purchasing their goods, to make out several lists and send to different stores to be priced, and then order at the lowest price in each list; and when it is known that the price of some of the articles, the same by name, varies at wholesale from twenty cents to two dollars a pound, the appeal to the *cupidity* of an *ignorant* apothecary is too great for his *conscience*.

In the simple article of *laudanum*, for instance see the difference in manufacture; opium quotations vary ten to twenty per cent.; when used moist instead of in powder, a loss of thirty to forty per cent.; then the difference in using avoirdupois instead of troy weight ten per cent. more, making fifty to seventy per cent. difference in price, and of course a corresponding difference in quality. And here the public are no better off, for they have to pay the same price, for the same cupidity which influenced him in the purchase will influence him in the sale. In these cases the apothecary makes no mistake; oh no, of course not, only an "error in judgment," but the patient dies. L.

Boston, March 5, 1881.

LETTER FROM WASHINGTON: SURGEON
GEORGE A. OTIS.

MR. EDITOR, — On Wednesday, February 23, 1881, died of apoplexy, at his residence in this city, George A. Otis, Surgeon and Brevet Lieutenant-Colonel United States Army. He was born in Boston, November 12, 1830, graduated with degree of A. B. and A. M. from Princeton, subsequently took up the study of medicine, and attended lectures at the University of Pennsylvania, receiving his degree of M. D. in 1850.

He then went to Europe, and spent several years in the medical institutions of London and Paris. Returning home he settled in practice at Richmond, Va., where he acquired a good business, and was one of the editors and assisted in conducting the *Virginia Medical Journal* in 1856, 1857, 1858, 1859. It was chiefly through the recommendations of Dr. Otis that Brown-Séquard, one of the most eminent physiologists of the time, was induced to accept a professorship in the Medical College of Richmond.

Having early acquired a preference for surgery, and become very familiar with the literature of this branch of medicine, he was led to seek a residence where there was more practice in this line of his profession. The extensive manufacturing establishments of Springfield, Mass., and the rapidly increasing population of the town, induced him in 1860 to take up his residence there. Here he rapidly acquired business and reputation.

Of great culture, retentive memory, and with a remarkable facility of expression, he was, as a compiler and writer, conscientious in his analyses, giving his deductions from the facts before him with modesty, but decision. With such a record it is needless to speak of his zeal, his ambition, or his devotion to his profession, and especially to the reputation of the corps of which he was so bright an ornament. He died while devoting himself to the preparation of the third and last

Surgical Volume (now more than half completed) of the Medical and Surgical History of the War.

From his settlement in Richmond, Va., he was a frequent and able contributor to the prominent medical journals of the country. His scholarly and professional attainments prominently pointed to him as eminently competent to edit the surgical volumes which have been issued by the surgeon-general on the surgery of the late war, the first of which was *The Surgical Report, Circular 6, S. G. O., on The Nature and Extent of the Materials available for a History of the War; on Amputation at the Hip-Joint; on Excision of the Head of the Femur; on Surgical Cases in the United States Army; on A Plan for Transporting Wounded Soldiers by Railway; on The Transport of Sick and Wounded by Pack Animals; also, A Check List of the Anatomical Section of the Army Medical Museum at Washington; and lastly two volumes, constituting volume II. of Part I. and Volume II. of Part II. of The Medical and Surgical History of the War of the Rebellion.* These two volumes place Dr. Otis prominently before the profession of the world as an able writer and a man of extensive reading and accurate knowledge of surgical history, and of the methods and procedures which have been practiced and are now deemed the best. A few of the most notable of his medical journal articles are: *Memorandum of a Case of Reamputation at the Hip, with Remarks on the Operation,*¹ *Observations on some Recent Contributions to the Statistics of Excisions and Amputations at the Hip for Injury,*² *Wounds and Operations, after Newberne, March 14, 1862.*³ Dr. Otis was for many years in close and frequent exchange of views with the leading surgeons and histologists in our own and foreign countries. He was a ready and graphic writer, but was not fluent as a speaker.

At the solicitation of Mr. Johnson, proprietor of Johnson's Universal Cyclopædia, Dr. Otis prepared the article on *Surgery* which is given in that work, and is an admirable *résumé* of the history and condition of the art up to the present time. Dr. Otis had a fondness for ethnology, and had all throughout his professional career been in correspondence with the leading ethnologists of the world. He was also on intimate terms of friendship with Jeffries Wyman, the leading ethnologist of our country since the death of Morton. Dr. Otis has left extensive manuscript notes on these subjects, and a remarkably complete anatomical cabinet and manuscript sketches of the various races of men collected from every part of the known world. He endeavored also to collect crania from the oldest burial places in our own and other countries. He was so methodical in his work that it is quite probable that his studies and manuscript will be found to be in such condition as to be utilized by others.

Appointed surgeon 27th Massachusetts Volunteers, September, 1861, he held this position until appointed surgeon, United States Volunteers, August 30, 1864. After the close of the war he entered the medical corps, United States Army, as assistant surgeon, February 28, 1866; became captain and assistant surgeon July 28, 1866; major and surgeon March 17, 1880, having received the four brevets of lieutenant-colonel of volunteers, captain, major, and lieutenant-

colonel, United States Army, for meritorious services during the war. While surgeon of the 27th Massachusetts Volunteers he served in Virginia, North and South Carolina, and was on special duty in charge of the hospital steamer *Cosmopolitan* in the Department of the South. Assigned to duty in this office July 22, 1864, he was curator of the Army Medical Museum, and in charge of the Division of Surgical Records until his death.

He was a member of the Virginia Medical Society, and represented it in 1852 and 1853 in the American Medical Association. He was also a member of the Massachusetts Medical Society, which he represented in the American Medical Association in 1860, and represented the United States Army in the same Association in 1865, 1868, and 1870.

He was a member and vice-president of the Anthropological Society, and member of the Philosophical Society, both of Washington, D. C. I regret that I am unable to give the names of the foreign societies of which he was a member.

Dr. Otis was not only a man of culture and social instincts, but always interesting and instructive, and one of the most delightful companions.

During the years that he has been identified with the Army Medical Museum he has frequently been consulted by our leading surgeons and pathologists in difficult and obscure cases, and was always courteous, and able to point to specimens and to the history of cases to illustrate his opinions, and of great help to the practicing physician and surgeon.

The doctor was married September 14, 1850, to Pauline Clark Baury, daughter of the Rev. Dr. Alfred L. Baury, of Boston; they had two children, daughters, who survive him, as does his mother.

His death, which was not entirely unexpected, was nevertheless sudden, as only last Saturday evening he attended the meeting of the Philosophical Society, and appeared to be in his usual health. His friends are numerous, and all have a kindly word of admiration for the man who so devotedly worked for the honor and elevation of the profession of medicine. His funeral took place from St. Matthew's Church, and was largely attended by the profession and by officers of the army and navy. His remains were deposited in Mt. Olivet Cemetery.

T.
WASHINGTON, D. C., February 26, 1881.

VALUE OF SCARS IN VACCINATION.

MR. EDITOR. — In your editorial of February 24th you quote Seaton's statement that those who have one or two good marks of vaccinia need revaccination much more than those with three or four. No distinction is made here, nor in Marson's table, between multiple primary marks, and those produced by successful revaccinations.

I have learned to distrust the practical value of scars, whether typical or not, as a guide to susceptibility to vaccinia in the individual. Indeed, the presence of several typical scars, resulting from successive vaccinations, might fairly be held to indicate a constitutional tendency to get rid of protective influences rapidly. Several instances of such idiosyncrasies have come to my knowledge. One is of a lady who has had four successful vaccinations at long intervals, with typical vesicles and scars. An infant was experimentally vac-

¹ *American Journal of the Medical Sciences*, Philadelphia, 1871, vol. lxi, p. 111.

³ *Boston Medical and Surgical Journal*, 1862, vol. lxxvi, p. 237.

minated from the last, with perfect result. The lady has had measles twice, and scarlatina three times.

Seaton's rule not to wait for an epidemic is good as far as it goes, but remembering that from atmospheric or some other influence the chances of success, in both primary and repeated vaccination, are much greater when an epidemic is present or impending, I believe it to be wise to take advantage of this influence and of awakened public attention to make protection as complete as possible. The objections quoted are not valid at the present day, in this country at least.

NORTON FOLSOM, M. D.

COLORED SIGNALS.

THE following note from a well-known professor of physics in one of our New England universities appeared in the *Boston Daily Advertiser* of March 8:—

As bearing on an important subject now being urged on the attention of the public, allow me to state a personal experience. I am "color-blind" to green, a defect of vision which in my case is slight, and might easily, with ordinary prudence, have been kept a profound secret. I have, indeed, more than once baffled

the off-hand investigation of scientific friends, though Dr. Jeffries, by means of Holmgren's worsted test, readily discovered both the nature and the degree of the imperfection. The following incident will show how utterly this slight degree of color-blindness unfits me for judging as to colored signals:—

I stood the other night waiting for a horse-car. One with a green light passed, going, however, in the wrong direction. I followed it with my eyes, the impression of the greenness of its lights remaining persistent. Approaching from a distance I now saw a car coming with what appeared to be red lights. The green lights and the red passed each other about fifty rods from where I stood, and, critically comparing them when side by side, I was convinced that one pair was green, the other red. When the approaching car had shortened the distance to about twenty rods, I suddenly observed that its light was green, as was indeed the fact.

Now it seems to me reasonable to insist that either colored signals are useless complications, and should be abandoned, or no one should be permitted to run a railway train who cannot interpret them better than can

Yours truly,

E. W. B.

Deaths reported 2783; 1048 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 530, consumption 433, lung diseases 408, diphtheria and

croup 199, scarlet fever 95, small-pox 55, diarrhoeal diseases 39, typhoid fever 28, cerebro spinal meningitis 26, measles 22, whooping-cough 21, malarial fevers 21, erysipelas 16, puerperal fever eight. From diarrhoeal diseases, Chicago 10, New York nine

Philadelphia five, New Orleans four, Brooklyn, Boston, and St. Louis two, Baltimore, Cincinnati, Pittsburgh, Somerville, and Newton one. From *typhoid fever*, Lawrence six, Philadelphia four, Boston three, Pittsburgh, New Haven, and Lowell two, New York, Chicago, St. Louis, New Orleans, District of Columbia, Providence, Worcester, Salem, and New Bedford one. From *cerebro-spinal meningitis*, New York eight, St. Louis four, Fall River three, Philadelphia and Chicago two, Brooklyn, Boston, New Orleans, Milwaukee, New Haven, Charleston, and Haverhill one. From *measles*, New York six, Boston five, Nashville four, St. Louis three, Baltimore, Cincinnati, Pittsburgh, and Charleston one. From *whooping-cough*, New York six, Boston three, Philadelphia, St. Louis and Worcester two, Brooklyn, Chicago, Baltimore, Pittsburgh, Lowell, and Fall River one. From *malarial fevers*, New York 12, Baltimore three, New Orleans two, Chicago, St. Louis, Cincinnati, and District of Columbia one. From *erysipelas*, Brooklyn three, New York and St. Louis two, Philadelphia, Chicago, Boston, Cincinnati, New Orleans, Pittsburgh, New Haven, Lawrence, and Somerville one. From *puerperal fever*, St. Louis four, Philadelphia two, Cincinnati, and Pittsburgh one.

Twelve cases of small-pox were reported in Brooklyn, 27 in Chicago, and 10 in Pittsburgh.

In 41 cities and towns of Massachusetts, with a population of 1,085,780 (population of the State 1,783,086), the total death-rate for the week was 21.99, against 22.79 and 22.17 for the previous two weeks.

For the week ending February 12th, in 149 German cities and towns, with an estimated population of 7,872,235, the death-

rate was 25.5. Deaths reported 3857; 2045 under five: pulmonary consumption 542, acute diseases of the respiratory organs 427, diphtheria and croup 150, scarlet fever 67, whooping-cough 64, typhoid fever 61, measles and röteln 60, puerperal fever 18, small-pox (Königsberg two, Lübeck, Munich, Aachen three) seven, typhus fever (Grandeuz, Posen, Magdeburg, Berlin) four. The death-rates ranged from 13.8 in Wiesbaden to 45.2 in Aachen; Königsberg 29.1; Breslau 27; Munich 30.5; Dresden 24.1; Berlin 22.5; Leipzig 18.5; Hamburg 27.5; Hanover 22.9; Bremen 19.5; Cologne 24.1; Frankfurt 24.3; Strasburg 30.9.

For the week ending February 19th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 22.4. Deaths reported 3267: acute diseases of the respiratory organs 364, whooping-cough 75, scarlet fever 68, small-pox (London 55) 56, fever 38, measles 35, diarrhoea 29, diphtheria 14. The death-rates ranged from 17.5 in Newcastle-on-Tyne to 28.5 in Sunderland; Birmingham 18; Sheffield 20; London 22; Bristol 23.1; Leeds 25.8; Liverpool 25.9; Manchester 28.3. In Edinburgh 24.3; Glasgow 25.1; Dublin 38.5.

In the 20 chief towns in Switzerland, for the weeks ending February 12th and 19th, estimated population 522,856, there were 40 and 42 deaths from acute diseases of the respiratory organs, diphtheria and croup 10 and 11, diarrhoeal diseases nine and 11, typhoid fever nine and eight, small-pox nine and five, scarlet fever three and one, measles two and none, puerperal fever one and one, whooping-cough none and one.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

Lectures.

ABSTRACT OF A LECTURE BY DR. GEORGE M. BEARD.

MESMERIC TRANCE.

On Monday evening, January 10th, Dr. George M. Beard delivered a lecture before the New York Academy of Sciences on Trance (so-called Hypnotism or Somnambulism); its Nature, Symptoms, and Varieties, with Special Reference to Mesmeric Trance; during which the phenomena of catalepsy, ecstasy, rigidity, and apparent death, partial and hemi-anæsthesia, aphasia, suspension and exaltation of mental and muscular force, and all the special senses, trance speaking and the Maine "Jumpers" were experimentally illustrated and explained. These experiments were conducted on a class of human subjects who had been under Dr. Beard's training, and with especial reference to the errors of prominent European observers.

Having spoken of the unreliability of inductive evidence and the necessity of deduction in such scientific questions, he stated that trance, properly defined, was a morbid functional condition of the nervous system in which all the nervous activity was concentrated in some special direction, with corresponding suspension in other directions. Nothing was super-added to, and nothing was taken away from, the natural powers of the subject; but, by reason of this concentrated nervous energy, results could often be obtained during the trance-state which were quite remarkable, and, to the ignorant observer, little less than miraculous. For convenience, and irrespective of its physical symptoms, he divided trance into four special types, — spontaneous, self-induced, emotional, and intellectual. It might be caused, he said, by the action of the mind on the nervous system, by disease of the brain, by exhaustion or starvation, by injuries to the brain, or by certain drugs, such as ether, chloroform, opium, and alcohol. The predisposition to this peculiar functional disturbance was either inherited or acquired; most cases of the spontaneous form having the former origin. He then illustrated the theory of the trance state by means of a chart containing three diagrams representing the human brain, each divided into three compartments. The first, or normal state of the mind, presented the separate compartments indicated by the numbers 50, 30, and 20 respectively; the second, the condition of sleep, in which the powers were reduced to 30, 15, and 10 respectively; while in the trance state two compartments became obliterated, and the third, intensified by the combination of all the normal faculties, was represented by the sum 100. If there were 100 units of force in the brain, all would be active in the natural state. In sleep they would be less active, and in mesmeric trance all activity would be suspended, except in one direction, in which all the nerve-force would be concentrated. The true explanation of the many and strange phenomena of trance, he continued, was one of the scientific questions of the hour. Its present prominence had been caused by two recent events in Europe, the march of Slade through England and the continent, carrying men of science with him into the domain of spiritualism, and, following, the careful investigation of trance by the European men of science. With regard to mesmeric trance — the type that had attracted most attention from the scientific world, and

which the Academy of Sciences in France had several times investigated without arriving at any satisfactory conclusion — he did not believe that any so-called animal magnetism or nervous influence emanating from the operator was concerned in its induction, but that it was purely a subjective condition, in the first instance, and that it was essential to the success of the operator that the subject should possess a sufficient basis of faith in him to admit of being affected or acted upon, not by the operator's nervous influence or aura, but by his own subjective emotions when his attention and expectation were concentrated upon any special matter. It was Dr. Baird, of Manchester, who had first proved that the phenomena of mesmeric trance are entirely subjective, and not objective; and this was the most important discovery ever made in this branch of science. For forty years the French Academy and men of science in other parts of Europe had been trying to find a satisfactory explanation of the subject, and had not yet succeeded; since they still clung to the idea that the cause was objective, and that bright buttons to fascinate and certain manipulations on the part of the operator were necessary to put the subject in the trance condition. The fact was that it was merely necessary for the operator to tell the subject that he was to go into this or that form of trance, and if the conditions were right, he would do so at once, even if the operator were to go and drown himself. It was by the action of the mind of the subject alone that the desired object was accomplished.

Infant prodigies, such as Shannon, the boy-orator, often went into a state of intellectual trance, and great orators and actors were also frequently in trance while before an audience. Beecher and Salvini were examples of this. The case of the Rev. Mr. Marshland, the Connecticut preacher, who disappeared from home and found himself a month later hired out as a workman in a different State, was one of spontaneous trance. When a modest and retiring individual came in contact with one energetic and bold, a reaction sometimes took place between them which might be compared to that which occurs among chemical elements and which resulted in the trance state. Thus, George Eliot, whom he had had the opportunity of meeting while abroad, was modest and retiring, while Lewes was her opposite, yet, although she was his intellectual superior, his influence over her appeared in a very remarkable manner in her writings. Emotional trances were the most common, and were produced by sentiments of fear, expectancy, wonder, or reverence. Alarms of fire and spiritualistic *séances*, therefore, were very potent as trance producers. Trance could also be induced in animals by means of fear.

The scientific value of the mesmeric trance was, that we could handle, test, and experiment with it, and by this means expose the secrets of all the other varieties. The facts had been known for a thousand years; but it was only now that we were beginning to get at the proper interpretation of them. Trance had often been confounded with sleep, and especially in a series of discussions which were carried on at Cambridge. In sleep, however, the activity of the nerve-force was lowered in general, while in trance, as had been previously stated, it was entirely suspended, except in one direction, in which it was correspondingly intensified. To further illustrate the theory of trance, Dr. Beard pointed out an analogy between the human brain and a gas chandelier. When all the lights were burning

freely, it represented the intellectual powers in their normal correlation and activity; when all were lowered, it represented natural sleep; and when all were turned down low but one, and that turned on in full force, it represented the trance state. When an individual was in trance we could do three things with every function that was under the control of the will—we could take it away, intensify it, or modify it in any way desired. The best subjects for mesmeric trance were modest, retiring, and sensitive persons, and aptness for the trance state was no evidence, whatever, of intellectual weakness. He then called attention to the faces of his class, explained that they were all strong and healthy and stated that so far from the trance condition being in any way injurious, he believed that it was positively beneficial to the physical organization.

During the foregoing remarks and after their conclusion Dr. Beard made a large number of very striking experiments upon his class of subjects, who had previously been under training to a greater or less extent. They were eight in number, and their ages varied from sixteen to fifty-five years. To a person in the trance state, he said, everything appeared different from what was ordinarily the case, and if one of his class was in the gallery and he were to point his finger at him, the subject would instantly leap over the railing in the attempt to reach him. For whatever the person in the trance state did, therefore, the operator was responsible; and the courts had to some extent so decided in certain cases of somnambulism. To show that the effect was psychological, and not physical, he had only to point his finger at one of the subjects, when the latter would follow wherever it led, even if it took him through fire or water. The subject might then be said to be fascinated, and all that was necessary to produce such a condition was that he should feel that the operator had a certain amount of power over him. Every one in the audience, he explained, could no doubt put some one else in a trance, and some of his assistants were more skillful than himself in exerting this power; though no one succeeded in all instances. In order that a satisfactory result might be obtained, it was necessary, as had been mentioned, that the subject should have a natural aptitude for the condition.

The counting and slight passes over the face used in producing the trance state were explained to be merely convenient methods of fixing the attention. Two of the subjects were then put into ecstasie trance, and gazed wonderingly up towards the ceiling, where, as they believed, a vision of angels appeared to them. In a third catalepsy of one side was induced, so that the arm would remain in whatever position it was placed, while in a fourth a state of complete muscular rigidity was produced. While in this condition he was carried about the platform like a log, and was then placed between two chairs, with the occiput resting upon the edge of one and his heels on the edge of the other. Finally, he was put in a perpendicular position against the wall, with his head resting on the floor and his feet up. This trance, Dr. Beard stated, though like death in its superficial aspects, could not be mistaken for it, since the respiration and action of the heart went on as usual, the latter, indeed, being usually considerably accelerated. The explanation was simply that the muscular structures were absolutely charged with an energy which was not subject to volition. Another experiment was now made to illustrate the muscular energy in the trance state. Taking up a

spring scale capable of indicating a weight of fifty pounds, Dr. Beard requested the youngest of the subjects, a slender lad of sixteen (then in his natural condition), to pull upon it at arm's length, when five pounds were registered by the index. He was then put in the trance state and told to pull. The effort made by him was not so perceptible this time as before, but no less than thirty pounds was registered on the scale. Hence, it could be seen that both quantitatively and qualitatively the muscular power might be modified while the subject was in this condition. It could be suspended, exalted, or modified at the will of a second person. The experiments in local anesthesia and hyperesthesia were also very successful. In one of the subjects Dr. Beard marked out just beneath the eye a spot about the size of a dollar, which he informed the young man he would render completely insensitive, while the rest of the face would be hypersensitive. Accordingly, it could be pinched between the fingers and pricked with pins until the blood came, without the slightest involuntary movement denoting the presence of sensation, while in the skin a hair's breadth beyond its boundary there was marked hyperesthesia. This test was also made by Professor Post, who pronounced that sensation was completely extinguished in the area designated. One of the strongest tests in this connection was the production of absolute anesthesia of the conjunctiva and cornea at will, and this had been repeatedly made at Dr. Beard's office by such well-known ophthalmologists as Professor Roosa and Dr. Webster. "As to anesthesia," Dr. Beard continued, "a subject while in the state of muscular rigidity just now exhibited might be chopped in pieces without feeling it." The eyes of one of the subjects were rather weak and extremely sensitive to light in the natural condition. The sensitiveness of the retina was very evident when a strong beam of light was thrown upon it from the ophthalmoscopic mirror. The pupil instantly contracted powerfully, and the utmost self-control was required on the part of the subject to prevent involuntary closure of the lids. When, however, he was put in the trance state not the slightest instinctive tremor of the eyelids or contraction of the pupil was noticeable when the intense beam of light was projected upon a retina which, as had just been seen, was abnormally sensitive under ordinary conditions. In the same way one eye could be rendered insensitive while the other remained in its natural state, and then the condition of the two eyes could be made exactly the reverse. Subjects were also rendered color-blind, first in one eye, then in the other, and finally in both eyes.

The tests in regard to the senses of smell and taste were equally satisfactory. When an unstoppered bottle of strong ammonia was held under the nose of one of the subjects he endured it with great composure, and said he thought it was cologne. In like manner he was not at all unpleasantly affected by the horrible odor of bisulphide of carbon while in the trance state, but when the same was held under his nose after he had been brought out of the latter his disgust was very amusing. The same subject drank tincture of gentian and other strong bitters supposing them to be syrups, and took cayenne pepper with evident pleasure under the idea that it was sugar.

The sense of hearing could be destroyed or modified with equal facility. Thus, one subject was rendered so deaf that he could not hear the sound of a large bell

ring or the report of a pistol discharged immediately at his ear, and another could hear only when sounds were produced near the back of his neck.

Trance speaking was fully illustrated in several of the subjects, who were quite incapable of making an extemporaneous address when not in a state of trance, but who when in this condition would speak fluently upon any topic suggested to them. In connection with this the instantaneous production of artificial aphasia was strikingly shown. When Dr. Beard would strike the subject lightly upon the back of the neck, or merely pass his hand downward in front of his face, the power of articulation would be instantaneously and absolutely suspended, in the very middle of a sentence or word, and the man would be unable to speak a syllable until the tap on the back of the neck was repeated or the operator's hand was waved in an upward direction before him, when the flow of language would be as instantaneously resumed at the exact point where it had been interrupted.

Further experiments were then made to test the perfection of the anæsthesia which could be produced in individuals in the trance-state, and they were certainly as convincing as any one could have desired. One of the subjects had previously agreed to allow the application of the actual cautery to his hand, and while the white-hot iron was in contact with it he stood calmly and unconcernedly without the slightest evidence of feeling it. Another subject, who had had the removal of three teeth previously advised by a competent dentist, had them extracted entirely without pain while in the trance state, and the dentist remarked that in thirty years' experience he had never before known an instance in which a tooth had been drawn without the patient's wincing, unless under the influence of an anæsthetic. Many other interesting experiments were shown which it is impossible to enumerate, and the final ones were in reference to the phenomena observed in the Maine "jumpers." After an allusion to "mind-reading," which he explained was merely muscle-reading, Dr. Beard concluded by saying that science always advanced at the expense of delusions. In this way astronomy succeeded to astrology, chemistry to alchemy, and physiology and pathology to witchcraft, while at the present day neurological science was fast superseding the delusions of animal magnetism, spiritualism, and mind-reading.

A CASE OF DIPHTHERIA FATAL ON THE THIRD DAY FROM CARDIO-PULMONARY THROMBOSIS AND (PERHAPS) EMBOLISM.¹

BY HALL CURTIS, M. D.

L. B., eight years of age. A strong and healthy child of emotional temperament, living on the bank of Charles River in a house whose drainage had been arranged last summer by Colonel Waring, was taken Saturday evening, February 12th, with sharp pain in the left ear. Sunday she complained of a sore throat, and remained in bed. The throat becoming more painful, she was seen by me at three p. m. The left tonsil was then quite red and swollen, with a patch of grayish membrane on its posterior half. There was also a decided glandular enlargement, with tenderness, below

¹ Read before the Boston Society for Medical Improvement, March 14, 1881.

the left mastoid. Respiration 28; temperature 101.8° F.; pulse 133.

Treatment: Ice-bag encircling throat; three grains of chlorate of potassium and ten minims of tinct. ferri muriatis in a teaspoonful of glycerine and water every two hours. She frequently of her own choice gargled her mouth with a solution of chlorate of potassium. The throat was painted every three hours with compound tincture of benzoin, while milk was to be given freely. At bedtime Dover's powder, five grains.

Monday, February 14th. During the night the child was restless, but at visit seems bright and cheerful. The pharynx is generally congested. The left tonsil is entirely covered by a grayish-white membrane. The glandular enlargement on this side has decidedly increased, while a similar adenitis has commenced under the right mastoid process. The temperature had fallen a degree, being 100.8° F.; respiration 21; pulse 125.

Four p. m. Has had a comfortable day, and taken milk and beef tea fairly. Ice-cream was refused, but champagne taken. Inhalations of steam were attempted, but, annoying child, were discontinued. Temperature 100.2° F.; respiration 26; pulse 116.

Tuesday, February 15th. The night was quiet; the patient in good strength and spirits. The periglandular swelling has now extended entirely round throat from ear to ear. The pharynx and tonsils are extremely congested, the latter much swollen and concealing the uvula. A thin film of membrane has extended from tonsil over left side of hard palate. Temperature 99.8° F.; respiration 20; pulse 100.

11.30 A. M. The film is rapidly extending on the roof of mouth. The membrane on left tonsil is thicker, but has become detached from the upper and anterior half of the gland. As it is hanging loosely, flapping to and fro in respiration and annoying patient, it is removed, followed by a slight sanious oozing. Membrane has formed on right tonsil.

Four p. m. Seen by Dr. T. B. Curtis in consultation. Looks pretty well, cheeks rather rosy; not flushed nor very pale; not sallow. Strength seems quite fair; is bright and cheerful; not prostrated; not irritable nor impatient; makes little complaint; docile. Pulse fairly strong, 100, even, regular. Respiration quiet and easy, not accelerated. Voice pure. Pain in pharynx increased by deglutition. Considerable enlargement of glands, especially over and under mastoid rather than under angle of jaw, bilateral, but most marked on left side. Puffy tumefaction of cellular tissue (periadenitis) encircling throat. Skin over swelling natural in appearance and color; little or no tenderness.

Fauces. Tonsils considerably enlarged, especially left. Membrane white, pearl colored, and grayish, extending up pillars on to velum. Uvula swollen and shiny, not coated.

Nares. No visible discharge, no redness of nostrils, no excoriation. Air passes on both sides with slight snuffling. Uses handkerchief more than usual. No epistaxis. No preauricular adenitis. Temperature 100° F.; respiration 24; pulse 100. Takes food, milk, beef tea, wine fairly.

Urine. Specific gravity 1030; acid; albumen absent. Nitrate of urea in albumen test of marked amount, that is, febrile.

Treatment continued. Brandy substituted for champagne, which the child now complained of, the carbonic acid gas troubling it in deglutition. Dr. Curtis advised

washing the throat every two hours with the fountain syringe, using an alkaline solution.

9.30 p. m. The throat has been washed without difficulty, the child assisting. Discharge from nose has increased. Child is now sleeping quietly and breathing easily, though she requires more pillows than heretofore. The pulse is good.

February 16th. Patient had a very restless night. Vomited Dover's powder, and complained of difficulty in breathing. Now seems tired and dull, unwilling to make any exertion, and inclined to doze. Has retained food, medicine, and stimulants. The face is rather pale, and a dark semicircle surrounds lower lid. Though the discharge from nose has increased the nasal cavities are clear. The membrane has become thick on right tonsil, and has extended over all the roof of mouth. The collar-like swelling of throat is unchanged. The temperature has fallen two and a half degrees; is now 97.5° F.; respiration 20; pulse 105, weaker.

12.30. Has had two slight struggles for breath, considered by her governess, who saw them, to be of a nervous character purely. Now sitting up in bed, the neck slightly stretched forward, the mouth open, and breathing with some little exertion, the nostrils dilating. No retraction at root of neck or at epigastrium. Voice slightly muffled from tonsular engorgement. Was interested in the washing of throat and nose, at times using the tube of the douche herself.

Four p. m. Dr. T. B. Curtis in consultation. False membrane size of quarter dollar on right tonsil. The membrane has partly disappeared from left side of fauces. Discharge from nose a little increased, but air passes; little or no snuffling. Epidermis of nostrils intact. No cough. No hoarseness. Voice pure (says 441 in loud, clear, unbroken tone); whispers to avoid pain in pharynx. A moderate degree of *dyspnoea*, with slow, labored breathing, with open nostrils, and no tirage is noticed. Patient is cheerful. Not anxious nor depressed; little evidence of prostration. Takes nourishment fairly well. Erythema over adenitis on left side of neck. Pulse 104, steady, even, regular, but not full nor strong; temperature 99° F.

Pacies as before. Mouth open, and moderate, not depressing *dyspnoea*. No *stertor*. No *stridor*. No signs whatever of *laryngeal* or other obstruction.

4.40 p. m. Sudden alarm. Just after Dr. T. B. Curtis and I had left the patient, we were summoned back from the drawing-room to the bedside of the child, who was said to be suffocating. We find her sitting up in bed, resting on her hands, the arms stiffened to their utmost, gasping for air, with labored inspiration, not very accelerated; pale and scared looking, signifying by gestures a wish to be fanned, eyes wide open and imploring; mouth opened to its utmost; *speechless*; no *tirage*; labored but *noiseless* respiratory movements. Soon violent contortions, generalized; patient throwing herself about, straightening out her back and legs; convulsion; opisthotonos; eyes staring open, with dilated pupils; pallor, soon ashy, then blueness of lips; pulse feeble, but regular. Respiration then ceased, and body and limbs became relaxed, the child sinking from the arms of her governess; pulse continuing, but growing rapidly more and more feeble.

Efforts were made to stimulate respiration, the mouth was opened, the tongue depressed and drawn forward with handle of spoon; chest bared and slapped with wet towel; artificial respiration by compression

of thorax and abdomen attempted, but without avail. At long intervals three or four inspiratory gasps were visible in the abdomen. The pulse gradually faded away; the heart silent. Death at 4.45 in the space of a few minutes (three to five).

There are many interesting features in the case just described. Symptoms usually found in the more advanced stages of the disease here appeared early.

Otalgia, the initial symptom in this case, depends on the propagation of the inflammation of the nasal cavities through the Eustachian tube, is therefore as a rule consequent to the disease in the pharynx. Trousseau¹ mentions a case where the child complained of excessive pain in the ear, particularly on coughing. He says in a large number of cases pharyngeal diphtheria spreads into the auditory canal by the Eustachian tube at the same time that it advances in the nose.

The *early glandular swelling*, when the corresponding tonsil only was invaded, may also be considered in a degree unusual. Jacobi² states when the tonsils are affected by the disease there is frequently little or no swelling of the neighboring glands.

Finally, death itself closed the scene rapidly and most unexpectedly by the formation of *cardio-pulmonary thrombi*, at the end of the third day of illness, instead of from the tenth to the twenty-first day, thus advancing the time of their usual appearance by seven to fourteen days.

Nothing in the child's condition gave any warning of the sudden end. Her strength had not been sapped, her spirits were good. Nourishment and stimulants were taken in fair amount; there was no prostration; the pulse gave no evidence of asthenia; no *epistaxis*; very little *fætor*, but no sign of septic poisoning. The voice was clear, breathing was not hurried nor accompanied by *stertor* or *stridor*; no pallor; no *tirage*. She died of asphyxia, but with open air tubes; not from want of air in the pulmonary vesicles, but from want of blood in their walls.

In the words of your president, respiration requires a rendezvous of air and blood in the lungs; either may fail at the rendezvous, and the phenomena of asphyxia are similar in both cases; with the exception of the absence of symptoms of destruction of air-passages, such as *stertor*, *stridor*, etc. The phenomena of asphyxia as described by Michael Foster are especially graphic:—

"As soon as the oxygen in the arterial blood sinks below the normal, the respiratory movements become deeper, and at the same time more frequent; both the inspiratory and expiratory phases are exaggerated, and the supplementary muscles are brought into play. As the blood becomes more and more venous the respiratory movements continue to increase both in *force* and *frequency*; very soon the *expiratory movements* become more marked than the inspiratory. Every muscle which can assist in expiration is in turn brought into play, and at last almost all the muscles of the body are involved in the struggle. The orderly expiratory movements culminate in expiratory convulsions. These convulsions, through which *dyspnoea* merges into asphyxia, are due to a stimulation of the *medulla oblongata* by the venous blood. Every intervening step may be observed between a *simple slight expiratory move-*

³ Michael Foster. Text-Book of Physiology. London, 1879.

ment of normal respiration and the most violent convulsion of asphyxia. An additional proof that these convulsions are carried out by the agency of the medulla is afforded by the fact that convulsions of a wholly similar character are witnessed when the supply of blood to the medulla is suddenly cut off by ligating the blood-vessels of the head. In this case, the nervous centres, being no longer furnished with fresh blood, become rapidly asphyxiated through lack of oxygen, and expiratory convulsions quite similar to those of ordinary asphyxia, and preceded like them by a passing phase of dyspnoea, make their appearance.

"Such violent efforts speedily exhaust the nervous system, and the convulsions after being maintained for a brief period suddenly cease, and are followed by a period of calm. The calm is one of exhaustion. The pupils dilated to the utmost are unaffected by light. All expiratory active movements have ceased, the muscles of the body are flaccid and quiet, and though from time to time the respiratory centre gathers sufficient energy to develop respiratory movements, these resemble those of quiet normal breathing in being, as far as muscular actions are concerned, almost entirely inspiratory. They occur at long intervals, like those after the section of the vagi, and like them are deep and slow. The exhausted respiratory centre takes some time to develop an inspiratory explosion. As time goes on these inspiratory efforts become less frequent; their rhythm becomes irregular, long pauses, each one of which seems a final one, are succeeded by several somewhat rapidly repeated inspirations. The pauses become longer, and inspiratory movements shallower. Each inspiration is accompanied by the contraction of accessory muscles, especially of the face, so that each breath becomes more and more a prolonged gasp. The inspiratory gasps spread into a convulsive stretching of the whole body, and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face drawn, and the nostrils dilated, the last breath is taken in. The heart beats are at first quickened, but speedily become slow, while at the same time they acquire great force. . . . The heart continues to beat for some seconds after the respiratory movements have ceased, the strokes at last rapidly failing in frequency and strength."

It is only within a few years that cardiac thrombosis and pulmonary embolism have been recognized and described as the cause of sudden death in fevers, in rheumatism, in diphtheria, and in the puerperal state.

Playfair's¹ account of the latter is strikingly descriptive. He writes, "The symptoms can hardly be mistaken. . . . In a large proportion of cases the attack comes on with appalling suddenness, which forms one of its most striking characteristics. Nothing in the condition of the patient need have given rise to the least suspicion of impending mischief, when all at once an intense and horrible dyspnoea comes on; the patient gasps and struggles for breath, tears off the coverings from her chest in a vain endeavor to get more air, and too often dies in a few minutes, long before medical aid can be had, with all the symptoms of asphyxia. The muscles of the face and thorax are violently agitated in the attempt to oxygenate the blood. The extreme embarrassment of the circulation is shown by the tumultuous and irregular action of the heart in its endeavor to send the venous blood through

the obstructed arteries; soon it gets exhausted, as shown by the feeble and fluttering beat. The pulse is thread-like and nearly imperceptible, the respirations short and hurried, but air may be heard entering the lungs freely. The intelligence is unimpaired during the struggle, and the dreadful consciousness of impending death adds not a little to the patient's sufferings and to the terror of the scene."

Pannum (quoted by Playfair) says (page 622), "The heart continues to beat after all (other) signs of life have ceased."

Labadie Lagrave,² in his monograph of one hundred and twenty pages on the cardiac complications of croup and diphtheria, recognizes two forms of attack, and makes a division into rapid thrombosis and slow thrombosis, according to the rapidity or slowness of its formation.

Rapid thrombosis. In the case where the cardiac clot has promptly attained a large size, and distends the heart walls now powerless to sweep it out or break it up, the symptoms are sudden, violent, unexpected, terrible. The little child raises itself up, is agitated, and throws aside its clothing; its face becomes pale, its features haggard, and the eyes express the deepest anguish. The skin is colorless, ashy, death-like. It seems as if all the peripheral circulation has at once and entirely ceased. The cardiac contractions, at first noisy and tumultuous, little by little grow confused, obscure, dull, irregular, and intermitting. It seems as if the heart, tired with its vain efforts, is ready to cease its fruitless work. The child's countenance bears the stamp of utter fatigue and exhaustion. The respiration is short, rapid, and panting, though the violent efforts of inspiration peculiar to mechanical dyspnoea are not found. Nor do the auxiliary muscles contract with energy. It is not air that is wanted by the lungs, but blood. The pulse is thready, feeble, at times hardly perceptible, irregular, and unequal. As the dyspnoea increases the limbs grow cold, a deadly pallor spreads over the body, and the child dies suddenly, or lingers in anguish during two to six hours. Fitz's³ cases are mostly of this kind.

Slow Thrombosis. When the clot is formed slowly, or when it is still small, the same symptoms may be observed, but in a much less striking manner. The difference in the intensity of the cause gives a different aspect to the disease. Still here, as in rapid thrombosis, the diagnosis must be formed from the symptoms taken collectively.

In this form, we again find the same pallor of the face, the same expression of fatigue, the same general ashy hue of integument, joined to an agitation often excessive. Dyspnoea is also very marked, but not from fault in the air-passages, the tirage is but little marked, the laryngo-tracheal whistling is feeble or nil. If tracheotomy has been performed there is no relief to the dyspnoea, you do not find the canula blocked by false membrane. Nor will the stethoscope show any pulmonary cause for the disturbance. It is impossible to find the slightest rational sign of asphyxia.

The fever of the commencement of the illness has now abated; in fact, is replaced by a certain amount of collapse, which may become more and more profound. The pulse is rapid, 136, 140, 158, but faint and feeble. The sounds of the heart are confused,

³ Fitz. Sudden Death from Embolism. The Boston Medical and Surgical Journal, vol. xvi., January 25, 1877, No. 4.

¹ Playfair's Midwifery. Philadelphia, 1880.

hesitating, at times reduplicated. Usually the first sound is muffled and somewhat prolonged. The general pallor becomes more and more marked, the chilling of the extremities extreme, and the respiration extremely rapid. The agitation of the first day, or of the first hours, gives way to depression and torpor, while death takes place in twenty-four or forty-eight hours; sometimes more tardily, in three or four days.

Picot and D'Espine¹ in their admirable *Manuel Pratique des Maladies de l'Enfance*, subject, Diphtheria, write that the heart is healthy in a large number of cases. At times it presents important lesions which have during the past few years attracted some attention. The most frequent is thrombosis; here the cavities of the heart, especially the right, are found filled with *organized colorless clots* adherent to the endocardium. *Endocarditis* is rarely found. *Fatty degeneration* of the cardiac fibres, often only very slightly marked, is found at times in children who die *while convalescing*.

The cardiac complications are difficult to diagnose. The accidents most often observed may be attributed to *thrombosis*, or more probably to a fatty degeneration or a paresis of the heart. They appear usually, but not always, at the beginning of convalescence, when all local symptoms have disappeared, and often in the course of a diphtheritic paralysis.

The symptoms are the same as those given by the writers before quoted.

Beverley Robinson² has written the most complete monograph on Cardiac Thrombosis in Diphtheria, published in Paris, 1873. He states that Werner,³ of Linz, in 1842, was the first to describe sudden death in diphtheria caused by heart clot. Winkler,⁴ in 1852, reported three. In England, Richardson,⁵ in 1856, was the first to portray the difference between an obstruction in the circulation and one in the respiratory tract. Barry,⁶ of Tunbridge Wells, in 1858, reported cases of fibrinous coagula, all of which were in the cavities of the heart. The following year Smith⁷ expressed his convictions that in certain cases of croup the symptoms must be referred to an embarrassed action of the heart, rather than to any obstruction in the larynx. Thompson,⁸ in 1860, considered cardiac thrombi *the most frequent causes of death* in diphtheria. Meigs,⁹ in 1861, also published observations on death following heart clot. Millard,¹⁰ Garnier,¹¹ and Gerlier,¹² in turn, furnished other examples. These cases were diagnosed before death, and the diagnosis was confirmed at the autopsy.

Robinson founds his paper on twenty post-mortem examinations made by him on children dying with diphtheria at the Hôpital Sainte-Éugénie from January 1 to June 1, 1872. He found coagula in seventeen cases in the right side of the heart, and gives a minute de-

scription of them. He is confident that they were not post-mortem coagula, nor formed during the death struggle.

The death struggle is characterized by asphyxia, which Claude Bernard and other distinguished physiologists consider especially unfavorable for cardiac clot forming.

These coagula were of a whitish color, in the right ventricle were fibrinous, and were not easily pierced by the finger. They were somewhat elastic and contained but little serum. Although resistant they were easily torn. Frequently they were formed by successive deposits of fibrine arranged in concentric layers. They showed the impressions of the *auriculo-ventricular opening* and its valves. Robinson believes that the *symptoms* show the *precise moment of this formation*, which without doubt depends on some pathological change in the blood, grows by successive deposits, and corresponds exactly to the troubles in the respiratory and circulatory system so constantly observed.

He gives an analysis of several cases:—

CASE I. Child in an advanced state of croup; vesicular respiration is heard, and resonance is good, but the child is asphyxiating; the trachea is opened without relief; the child is agitated; its cheeks, lips, and hands faintly livid. The next day he is fatigued; the pulse is feeble, at times irregular, but respiration is quiet. The next day the child is cyanosed and excited. The heart-beats are weak without souffle; not intermitting; area of cardiac dullness increased. The pulse becomes more frequent, is very small, still there is very little irregularity in its force or rhythm. The skin of the trunk and extremities is very pale, contrasting strongly with the cyanosed finger ends, the cheeks, and lips. Pulmonary resonance at the base is still good; almost increased. In a few hours the child is dead.

CASE II. Tracheotomy; the same evening oppression; the canula was changed without relief; symptoms of cardiac asphyxia; though the heart-beats were strong the pulse was almost imperceptible; the child was rational, but died in a few minutes.

CASE III. Tracheotomy followed by relief; the next morning the skin was cool, pulse small but regular, inspiration silent and full; shortly after the visit the child became agitated, and in three hours was dead.

CASE IV. The night following tracheotomy was poor; the next day the face was pale; pulse and breathing rapid; but vesicular expansion sufficient. That evening the child became restless, seeking apparently a more easy position for breathing and sleep; gradually failed and died in twelve hours.

CASE V. The sixth day after tracheotomy everything seemed to be doing well; the child eating freely, breathing normal, wound healthy, no albaumen; when at four p. m. the pulse became rapidly feeble; the child sitting up pale and restless; breathing rapid but regular; at four the next morning the child died, after an extremely agitated night, but rational to the end.

CASE VII. Child four years old with diphtheritic coryza and pharyngitis, *died almost instantly* on the seventh day of his illness. The day before his death the lesions were confined to the nose and pharynx; vesicular breathing throughout chest; that evening the skin became ashy. Early the next morning the child asked for drink. Being raised into a sitting posture, he

grew waxy pale, settled down, fell back; there was no struggle, no convulsion, a few feeble and intermitting beats of the heart, a few incomplete inspirations, and all was over.

CASE VIII. A little girl, six years old, after two days' illness was admitted, with a history of cough oppression, and false membrane on the posterior wall of the pharynx. On the eleventh day became alarmingly pale, and would not eat; still there was nothing abnormal to be detected. That evening she died quite suddenly, without any convulsive movement. One hour before death the pulse was small and thready; the heart sounds muffled; the body extremely pale; respiration frequent but without stridor.

Why a thrombus should at times cause death rapidly and at others slowly is easily understood. The clot is not always formed in the same place, nor in the same time. The cardio-graphic examinations of *Chauveau* and *Marey* prove that the heart may contain bodies of considerable size in its cavities without recognizable symptoms.

Richardson also says coagula may be formed very slowly, layer by layer, and many days may pass without their presence being revealed by a single physical sign.

In these cases the circulation becomes embarrassed by degrees, the valves continue to work for some time, and death follows after a long struggle. At other times the coagula may form slowly at first, but rapidly towards the close. In these cases the existence of the thrombus may not be revealed for some hours or days, though finally and suddenly we become aware of it by the restlessness, anxiety, and anguish, which continue without break to the end.

Sanné,¹ in his *Treatise on Diphtheria* (Paris, 1877), is the only author who denies the fact that death is caused by thrombi. He denies that the clots have the characteristics of those formed during life; he affirms that they are formed in other fatal diseases, where there have been no cardiac symptoms, and where they are traced in patients dying with diphtheria they are always associated with pulmonary lesions. He acknowledges that the symptoms arise from the heart; the præcordial pain, the pulse variations, the tendency to syncope, and the heart-beats indicating the cardiac origin. He believes these cases are very rare, and attributes them to a diphtheritic paralysis; for they never occur at the commencement of the illness, but from the tenth to the twenty-first day, when convalescence is fully established.

Other authors, as *Oertel* in *Ziemssen's Cyclopædia*, *Lorain* and *Lépine* in the *Nouveau Dictionnaire*, *Sennator*, on *Cynanche Maligna*, in *Volkmann's Clinical Lectures*, say nothing of thrombosis.

Cause of Death: *Virchow*² attributes it to syncope, depending on stoppage of the cardiac contraction. *Panum*,³ on the other hand, contests this view, maintaining that the heart continues to beat even after all signs of life have ceased. His theory is that death is the result of *cerebral anæmia*. To this view agree *Michael Foster* and also *Wagner*. *Wagner*, in his *General Pathology*, states that sudden death in severe embolism of the pulmonary artery depends upon the want of blood-supply to the brain and medulla oblongata. In this it is a question neither of suffocation

nor of paralysis of the heart. In extensive embolisms of the pulmonary artery, the first quite constant phenomenon is the extreme paleness of all visible parts of the body (conjunctiva, gums, lips). The white brain-matter is entirely empty of blood. The veins and venous sinuses of the brain are filled with blood. This paleness is immediately followed by constant titanic extension of the limbs, involuntary evacuations of the urine and feces, and very deep inspiratory movements.

Diagnosis. *Playfair* states that in twenty-five cases of sudden death after delivery, in which careful post-mortem examinations were made, seven gave evidence of true embolism. In these death occurred late, in none before the nineteenth day.

In fifteen cases death occurred before the fourteenth day, often on the second and third days. In these cases there was no embolism, but a thrombosis. He believes that spontaneous thrombosis and true embolism may be divided from each other by a clear line of demarcation, depending on the period after delivery at which a fatal event takes place.

*Picot*⁴ and *D'Espine* consider the cardiac complications difficult to diagnosticate. They appear usually, but not always, at the beginning of convalescence, when all local symptoms have disappeared, often in the course of a diphtheritic paralysis.

Maurice Raynaud,⁵ article *Cœur*, *Nouveau Dictionnaire de Médecine et de Pratiques Chirurgie*, vol. viii. p. 574, remarks on the Diagnosis of Cardiac Thrombosis and Pulmonary Embolism, that the differential diagnosis between cardiac coagula and pulmonary thrombi, or emboli, presents almost insurmountable difficulties, and can be based only on probabilities.

Robinson lays stress on the resonance, at times hyper-resonance, of the chest.

Richardson states that in children especially you find marked symptoms of emphysema, without any sign of congestion or hepatization; he considers this an evident demonstration of the existence of the thrombus.

Hope,⁶ *Richardson*, and *Robinson* all draw attention to the peculiar dyspnoea; that is, dyspnoea with open air-passages, asphyxia without obstruction of respiration, only to be explained by its cause, — the thrombus. It takes place not because the movements of the chest are fettered, not because the access of air to the lungs is checked, — for the respiratory murmur is distinctly heard, — but because the quantity of blood furnished by the pulmonary artery is diminished.

Robinson. The diagnosis of intra-cardiac coagula must rest on the general and local symptoms observed with care. Of the first are the chilling of the extremities, the pallor, the prostration, anxiety and agitation, the feeble pulse, and characteristic dyspnoea. The local symptoms are the dull, muffled, weakened heart pulsations and the emphysema of the lungs. He draws the following conclusions: —

(1.) That cardiac thrombosis is a frequent complication of diphtheria.

(2.) That the elastic fibrinous coagula entangled in the valves, or adhering intimately to the walls of the heart, are formed before death.

(3.) That they are formed often before the death struggle.

(4.) That they cause symptoms of the gravest nature.

(5.) That their prognosis is important both for treatment and prognosis, since on the one hand their presence renders a fatal issue almost certain, and on the other renders the operation of tracheotomy useless and needless.

(6.) That the polypoid-shaped clots are often the proximate cause of the serious state of the patient, and not the result of that condition.

(7.) That death may occur suddenly, immediately after its formation, or after a stage of anxiety and of anguish, lasting for a longer or shorter time.

RECENT PROGRESS IN INSANE ASYLUM MANAGEMENT AND CARE OF THE INSANE.

BY WALTER CHANNING, M. D.

AN ENGLISH ASYLUM.

THE Twenty-Eighth Report of the Derbyshire County Lunatic Asylum is one of a good class of English reports, and worthy of mention in a review of literature. The asylum contained, at the end of the year 1879, 414 patients; with this large number the superintendent, Dr. J. Murray Lindsay, was able to do the usual routine work of supervising and building, and, in addition, some excellent scientific work. The number of admissions was large (180), and yet he received the assistance of only one medical officer. It is hard to understand how he could accomplish so much, unless the steward and others managed more of the asylum affairs than is common in this country. The asylum contained the large number of 74 epileptics, and, what is unusual in America, several idiot children. Dr. Lindsay states that hereditary predisposition was ascertained in nearly twenty-five per cent. of the admissions, but this per cent. does not, in Dr. Lindsay's opinion, represent to the full extent the part heredity plays in the causation of insanity. Intemperance was the assigned cause in eighteen per cent. of the cases.

The percentage of recoveries was forty-five on all admissions; forty-six males recovered to thirty-five females, which is regarded as a remarkable feature of the year, and certainly still more remarkable in contrast with our asylums, the proportion being quite as great in favor of the females. The same unusual feature presents itself in the preponderance of deaths in the females. The general mortality is so high that it at once arrests attention, there having been 70 deaths out of a total of 602 treated. Comparing these statistics with those of other hospitals, we find that at Danvers of 875 under treatment 63 died; at Taunton of 752, 48 died; at Worcester of 656, 36 died; at Northampton of 535, 23 died. At the California State Lunatic Asylum, the twenty-eighth annual report of which has just come to hand, there were treated during the year 1241 patients, and of these 72 died. While the Danvers percentage approaches somewhat nearly that of the Derbyshire Asylum, those of the other hospitals are little more than half. The asylum is about six years older than the Northampton Hospital; this would ensure more deaths from old age and chronic diseases, but on the whole a smaller mortality than if it received a greater number of acute cases. We find that there are nearly three times as many deaths at

the former as at the latter, though treating only sixty-five more patients a year. One third of the deaths were caused by paralysis and consumption.

It is pleasant to turn to the scientific work performed at this asylum. The American reader will be struck by the fact that 65 autopsies were made out of 70 deaths! In this country, owing to public feeling and professional inertia, the number would not be more than one third as great. Under the heading of Medical Notes and Statistics a number of interesting experiments were made. Trials of *sumbul*, potassium bromide, zinc, arsenic, amyl nitrite, and nitro-glycerine in cases of epilepsy were made. The number of cases was forty, many of an unpromising nature, and all accompanied by mental alienation. *Sumbul*, arsenic, and zinc were found, on the whole, to produce no effect in diminishing the frequency or severity of the fits. Amyl nitrite was found of benefit in a few cases, particularly in well-marked anæmic cases, where potassium bromide was not as useful. The amyl nitrite was prescribed in half to three minim doses three times daily, in an ounce of water. "A trial was made of nitro-glycerine, on the suggestion of Crichton Browne, of a one per cent. solution in alcohol. On the whole it did little or no good, and even made some cases worse." Potassium bromide alone was found to be of certain and rapid benefit. It is stated that there were several deaths in the epileptic status, and these led to the trial of chloroform for the purpose of preventing the recurring convulsions and deepening coma. In the case reported it was successful.

In the sixty-five autopsies made during the year the condition of the osseous system, with special reference to the fragile, brittle, or softened condition of the ribs and sternum, was carefully noted as follows: "The ribs and sternum were noted as abnormally fragile and weak in eight males and sixteen females, — in some cases so weak and soft as to break or bend (green-stick fracture) with very slight pressure. The influence of the nervous system over bone-nutrition and the frequency of a diseased condition of the osseous in the insane, as bearing upon the liability of fracture, are very important in a medico-legal point of view, for broken ribs do occasionally occur in asylums, and it is popularly supposed that extreme violence on the part of attendants or others is always necessary to produce them."

Brain weights had been taken during eight years in 120 cases. The average weight of the brain in 250 male lunatics was 47½ ounces, about two ounces less than the healthy average, according to Quain. The average weight of the female brain was 43¾ ounces, or one quarter of an ounce less than the healthy brain. The largest brain was that of a general paralytic, and weighed 60 ounces, and the smallest was that of a female epileptic idiot, and weighed 25 ounces. These results accord with those of Dr. Boyd, Dr. Thurnam, and Mr. Crochley Clapham. Dr. Crichton Browne finds a greater difference in the male and female brain, and agrees with Broca that the smaller size of the female brain depends as much on her intellectual as on her physical inferiority. Dr. Lindsay finds the left hemisphere the heavier in the proportion of five to four. Brown-Séquard and Dr. Boyd agree with this view, but Dr. Crichton Browne, Dr. Thurnam, and Prof. Wagner, find the right the heavier.

I cannot close this long review without referring to the cost of the tobacco, beer, and wine used at this

asylum. The cost of these articles so far exceeds that of our American insane hospitals that one is struck by the contrast. The tobacco and snuff bill for the year was £93. The cost of the beer, ale, and wine £666 16s. 6d., or only £80 13s. 6d. less than the cost of the butter, cheese, bacon, and eggs. In the list of provisions meats come first, flour second, and tobacco, beer, ale, and wine third. In this country but little beer or wine is used, brandy and whisky being the staple articles. These are generally put down under the head of "drugs" or "medical supplies." Looking at the Massachusetts hospital reports for 1879 we find no mention of liquors or wines, but the total cost of medical stores in the five hospitals was only \$5265.03, or about £1053. Here it must be stated that "wines, spirits, and porter" are, in the Derbyshire Asylum report, called "extras for the sick." Adding the cost of these to the above cost, of "ale, beer, and wine" found under the heading of provisions, we get a grand total of £795 4s. 6d. Adding still further the cost of "drugs and instruments," which is £105 2s. 7d, we find that the difference between the cost of medical stores and stimulants at an English asylum having in the course of a year 602 patients under treatment is within £150, in round numbers, of the cost of the same articles for 3240 patients in Massachusetts. If we leave New England and go toward the West, we find stimulants more used; for instance, at the Northern Hospital for the Insane at Winnebago, Wisconsin, their whisky, wine, and gin bill, which comes in under the head of "drugs and medical supplies," amounted in 1879 to \$1226.70 for a total of 757 patients.

CURABILITY OF INSANITY.

Dr. D. Hack Tuke, of London, has an important article on Tabulating Recoveries from Insanity, in the *Journal of Mental Science* for October, 1880. He reaffirms the conclusions arrived at by Dr. Earle, that the number of recoveries reported in asylum statistics is far from correct, and gives rise to much misconception as to the actual number of persons who recover from insanity. Dr. Tuke states that he does not object to superintendents making as good a showing as possible; repeated cures of the same patient often show great skill of treatment, but some better system of figures is necessary, as the public are now made to believe that "100 recoveries represent 100 persons enjoying the use of their reason, instead of, in too many cases, oscillating between the world and the asylum. Then in their ignorance of the tendency to the recurrence of insanity, they are astonished at the ever-increasing demands for new asylums and the conclusion, out of all proportion to the fact, that there has been an increase of insanity." Speaking in another place of the great number of relapses, Dr. Tuke says: "Taking the recoveries from the first attack at the York Retreat, up to a certain date, as many as sixty-five per cent. relapsed, some of course recovering again. The cures at first were fifty-three per cent.; then after deducting relapses they were only eighteen per cent., while allowing for recures the latter number was raised to eighty per cent."

Dr. Earle, in his annual report of the State Lunatic Hospital at Northampton for 1880, again devotes considerable space to the subject of the curability of insanity. As an illustration of the mistake which may result by drawing inferences from statistics, under the head of "instructive statistics" he gives some re-

markable information regarding 118 cases of insanity which have been treated in American hospitals, and the statistics of which have been published in the annual reports of those institutions. Dr. Earle says: "If Dr. Todd's well-known group of 23 cases at the Hartford Retreat, and Dr. Galt's group of 13 cases at Williamsburg, Va., were sufficient in number to justify the inferences in regard to curability which were drawn from them, and which were largely influential in establishing a prevailing belief, then may we safely be permitted to derive some inferences from this group, which is more than three times as numerous as both of them." Four tables Dr. Earle gives, one being *age on admission*; one, *age on first admission*; one, *occupation*; and one, *results of treatment*. We find from these tables that insanity prevails only among females; that under forty-five years it is very rare, but prevails to its greatest extent among those of from forty-five to sixty years; that first admissions occur oftenest from forty-one to forty-five years, and least frequently from twenty-six to thirty years; that of all females the wives of manufacturers are the most prone to become insane; that insanity in females is one of the most curable of all diseases, 102 out of 118 recovering, or 86.44 per cent.; that of the 118 patients only one died, or eighty-four one hundredths of one per cent. We learn further that all these patients were married, the inference of which would be that mental disorders are apparently unknown among unmarried women. The explanation of these wonderful statistics is that these 118 cases of insanity relate to three persons, all of the unmarried women! These three women were admitted to hospitals 118 times and discharged as recovered 102 times. One of them died insane in a hospital; another died insane at home; and the third at the age of seventy-five years has entered an almshouse.

RESTRAINT.

Dr. Brosius, editor of the *Irenfreund*, in numbers 2, 3, and 4 for 1880, discusses fairly and candidly the question of non-restraint. He strongly urges the use of seclusion as a substitute for restraint. He proposes large, comfortable seclusion rooms (*zellen*), with which should be connected large yards, in which the secluded patients could be allowed to wander freely. As a further means of non-restraint there should be a set of perfectly trained attendants, who should, "*leidenschaftlos mit Entschiedenheit und Klugheit die ärztlichen Anordnungen ausführen.*"

After enumerating the various forms of disease where seclusion will be beneficial, Dr. Brosius says that it should not be continued too long. The patient forms bad habits, and sometimes acquires delusions which can only be broken up by removing him from the seclusion. He can then be carried back to the other patients, or kept apart in the corridor connected with his room, which should be pleasantly furnished and entertained by his attendant. In certain cases, however, restraint will be necessary; "even Connolly himself speaks of exceptional cases." Particularly when the patient shows a determination to harm himself by injuring his flesh, picking the finger nails, pulling out the hair, etc., Dr. Brosius recommends the occasional use of gloves. He criticises those persons who use gloves and yet do not call them restraint; it would be more proper to say they could not get along without restraint. "In cases of chronic propensity to self-injury, manual restraint continued

for months is not possible, and it would be a much worse and more unbearable form of restraint than gloves. The patient bears these with comfort, goes where he will, and has free motion, whereas the attendant who holds him is a constant burden, who irritates him, and is irritated by him, and with whom he creates so much confusion that it is better for him to remain away from the other patients, among whom his gloves would not have seemed at all strange." As a very important means of keeping patients quiet, Dr. Brosius dwells at some length on good food. "The kitchen and the wine cellar are of much greater importance and influence than the apothecary shop. Liberal diet and a fine strong wine are on the whole better and a more adaptable form of quieting medicine to the system than the various narcotics, such as chloral, potassium, bromide," etc.

In the *Centralblatt für Psychiatrie* for January, 1881, Dr. Rahow reviews a paper written by Billod and presented at the recent International Congress at Amsterdam, on Restraint and Non-Restraint. Billod says the English and French hold much the same views on the subject; but restraint—especially the camisole—is often employed in France. In Holland, also, but very little restraint is used. Billod accounts for this by the different characters of the different countries. Then, too, in England and Holland food, liquors, or beers and tobacco, are extensively used. It is a well-known fact that food is one of the most important means of producing quiet. In England, too, the fear and respect in which state officials are held exerts a strong influence in promoting quiet.

Dr. F. Pritchard Davis, superintendent of the Kent County Asylum, writes a short article in the *Journal of Mental Science* for January, 1881, on the subject of Chemical Restraint and Alcohol. He believes that a change in the use of chemical restraint is following mechanical restraint. In the asylum over which Dr. Davis presides there are over 1200 patients, and among them cases of every variety of insanity, but for fifteen months no quieting medicine at all has been used. The results have been so good that probably none will be used in the future. Part of this success is probably owing to the disuse of alcohol, none having been used except with the very old and feeble. In speaking of the use of drugs Dr. Davis goes so far as to compare the use of hyosciamine to that of the garrotte, and asks if one plan of treatment would not be as admissible as the other. Chloral is anything but an unmixed blessing and has probably thrown back the rational treatment of insanity several years.

CRIMINAL LUNACY.

In the January number of the *Journal of Mental Science* there is a Review, continued from the October number, of papers and discussions on this subject presented at the International Congress of Mental Medicine. Dr. Auzouy discusses the risk of discharging homicidal and epileptic criminal lunatics. He recommends that criminal lunatics should be tried like ordinary lunatics, and sentenced and confined in special asylums for a term at least equal to that of the imprisonment they would have suffered if responsible. Dr. Dagonet refers to the frequency of epilepsy in criminals, and regards its occurrence as of the greatest importance. He thinks that so-called criminal lunatics ought not to be any more than any other lunatics subjected to constant confinement, merely because they

have committed a criminal act. Their having been dangerous once does not necessarily imply that they would be so a second time. Dr. Lanier does not think there is as much difference between those who became insane before commitment and those who became insane in prison as might be thought.¹ He thinks that one quarter, at least, of the convicts found insane in the prisons were so at the time of being condemned.

He thinks it improper to commit criminal lunatics to ordinary asylums; they should be treated in special asylums, but convict lunatics he considers it more convenient to leave under the care of the penitentiary administration in a special building.

The reviewer, in considering the various papers, thinks Dr. Dagonet expresses too great confidence in the freedom from second attacks. Particularly should we guard against epileptics (in the reporter's experience the most dangerous class of insane criminals). The reviewer says that "rather than admit that chances of peril (from epileptics) are so improbable, we always, on the contrary, believe, with Delasiauve, that 'on passing by an epileptic we elbow one who might be an assassin.'" So, also, is it in the highest degree necessary to be on the lookout for the maniacs who "exhibit no intellectual disorder to indicate a threatening danger of the outbreak of fierce violence."

GHEEL.

Under the title of The Town of Gheel in Belgium and its Insane, Dr. William J. Morton writes an instructive as well as a fresh paper in the *Journal of Nervous and Mental Diseases* for January, 1881. He visited Gheel last summer, and made a careful examination, and presents details which have not been so thoroughly gone into by previous writers. Our old-fashioned idea of Gheel was a rather small town, composed chiefly of peasants, in which the insane were farmed out under little medical supervision; if violent, fastened with chains, and generally largely at the mercy of the peasants. The case now, however, is different, and, as bearing on the question of provision for the insane, is worthy of notice in this report.

Gheel is twenty-four miles from Antwerp, and is easily reached in one hour. Its inhabitants are Flemands intermixed with Germans and Gauls. The population of the town is 12,000, chiefly centered in the town, though there are some outlying hamlets. The insane population has steadily increased, being, in 1868 1035, in 1880 about 1600; 1400 of these are Belgians, the rest Hollanders, Germans, French, and English. Two hundred are paying patients. All cases not of a violent or dangerous character are received. Up to 1851 there was no organized medical service. At that time Gheel was placed under the control of the central government. The administration rests in the hands of a "superior commission;" added to this commission there is a secretary. He is, it might be said, the steward or clerk, and makes reports, conducts the correspondence, receives and disburses funds for the patients' maintenance, and has charge of the books. The real working portion of the commission is its permanent committee, composed of five members.

¹ The reporter wishes to call special attention to this statement as being contrary to what is often asserted by those who have not had large numbers of both classes under treatment. Those who have, fully endorse what Dr. Lanier says.

All persons desiring to keep patients must be registered on the list authorized by the permanent committee. Those receiving paying patients are termed "hosts," and those receiving paupers "nourriciers." Both classes must be of good moral character, and cannot receive more than two patients. The size of the room, the quantity and quality of the food, the ventilation, clothing, bedding, and furniture are all definitely prescribed. Care is taken to place patients in families in like social circumstances, and the labor of patients is carefully regulated. To guard against abuse there are "section guards," whose duty it is to visit the various patients continually and unexpectedly, and make daily reports.

The medical service is under the charge of a "medical inspector;" at present Dr. Peeters, successor of Dr. Bulkens. He is saved from attending to matters of financial detail by the secretary.¹ His headquarters are at the infirmary, to be shortly mentioned. He is assisted by three physicians, who have charge of the three sections into which the town is divided. These physicians reside in these sections, and engage in general practice. Each one must visit the curables at least once a week, and the incurables once a month, and both classes oftener if needs be. The physician's visit is entered in a book kept by the nourricier or host, and he makes a monthly report to the inspector. The infirmary is like an ordinary asylum. Its purpose is to afford the usual hospital treatment to patients attacked with incidental diseases, to care for the very infirm, and to take brief charge of cases becoming suddenly excited. But the patient's stay is expected to be temporary, and from the small number under treatment (thirty-seven) it must be so.

A peculiar classification is made of the insane at Gheel, which serves as a basis of payment to the nourriciers or guardians. There is first, the dirty class; second, the half dirty class; and third, the clean class (gateux, semi-gateux, and propres). For the first class about nineteen cents per day is paid; for the second, eighteen, and for the third sixteen. Some private patients pay six hundred dollars yearly.

Escapes are very rare, ranging from only seven to twelve annually. Acts of violence are also rare, only three being on record, and only one of these a homicide, in 1840.

There have been three suicides since 1875. In a half century scarce a half dozen pregnancies have occurred.²

Dr. Morton found only one patient in restraint in the form of a camisole, the use of which had been sanctioned by a section physician.

In 1879 three hundred and thirteen patients were admitted, of whom seventy-one were incurable. The proportion of cures from 1853-70 was twenty-four per cent. In estimating cures, the large number of chronic patients received must be borne in mind.

In speaking of the feasibility of the Gheel system in America, Dr. Morton truly says, "the Gheel of to-day is the product of tradition, superstition, religion, and long custom. Gheel was not born fully equipped for its service, it grew. . . . Gheel in its entirety is probably an ideal that can never be produced in any other country."

Hospital Practice and Clinical Memoranda.

SOME SURGICAL CASES AT ST. JOHN'S HOSPITAL.¹

SERVICE OF JOHN H. GILMAN, M. D., LOWELL.

FRACTURE OF FRONTAL BONE OF SKULL NEAR JUNCTION WITH RIGHT PARIETAL, FRACTURE OF RIGHT RADIUS AND ULNA AT MIDDLE THIRD AND AT WRIST; COMPOUND FRACTURE OF LEFT RADIUS AND ULNA AN INCH AND A QUARTER ABOVE WRIST JOINT. RECOVERY.

October 30, 1880. J. E. J., a lad fourteen years of age, during the dinner-hour of the operatives of the Merrimack Mills, with a few boys about his own age, interested himself in the new mill in process of construction in the yard, more especially in an apparatus for raising bricks and mortar to the upper story. To the end of the long rope, that aloft ran over a pulley, a stick was fastened which J. E. J. got astride, and was drawn up forty-eight feet, when the stick broke, precipitating the unfortunate boy to the ground, striking on his head and hands. Two hours after the accident he was brought to St. John's Hospital in an insensible condition from concussion of the brain, and presenting altogether a hideous appearance, with bloody visage, black swollen eyelids, gaping wounds, and broken limbs. The fractures of the right forearm were reduced, and appropriate splints applied; but it was found quite impossible to reduce the compound fracture of the left forearm without sawing off half an inch of the protruding radius, which being done, reduction was effected, and an exterior or dorsal splint, extending from near the elbow to the end of the fingers, was applied and retained in place by strips of adhesive plaster carried around the arm at proper intervals, leaving the wound on the anterior aspect uncovered, which was dressed with absorbent cotton wet with a solution of carbolic acid 1 to 32, and then the whole forearm was bandaged. There was considerable depression of the vault of the frontal bone at the seat of the fracture of the skull, but it was deemed best not to resort to any operative procedure to raise the bone unless there should arise symptoms of compression. The hair was cut short, and compresses wrung out of ice-water were applied to the head. He was confined to a milk diet. The life of the patient hung, as it were, by a thread for the next few days, but he gradually recovered consciousness and strength, so that at the end of a week he appeared to be quite in possession of his mental faculties and in a fair way to recover. About this time the swelling of the eyelids had so far subsided as to enable the patient to open his eyes, when the right eye was found to be blind; though previous to the accident the sight was normal in that eye. The patient mended steadily till November 13th, two weeks from time of the accident, when he complained of headache, was irritable in temper, and had less mental vigor than on the previous day. A purgative enema was given without any marked benefit. The next day, about seven o'clock in the morning, the patient became suddenly convulsed, one convulsion following another in rapid succession. Upon arrival at the bedside, shortly after eight o'clock, I found the patient still in convulsions,

¹ Is he? All American insane hospitals have stewards and clerks, but the superintendents still have numberless business details to look after.

² Lettres Médicales sur Gheel, etc. J. H. Peeters. Gheel. 1879.

¹ Read before the Middlesex North District Medical Society, January 26, 1881.

insensible, and nearly pulseless. About two drachms of ether was poured upon a handkerchief and administered by inhalation; this quantity speedily stopped the convulsions, and they did not return afterward. The respirations were slow, shallow, and halting, the expirations being prolonged, so that it was necessary for an attendant to stand by and give the chest an occasional jog for nearly two hours, after which the respirations became more regular and went on unassisted. Meanwhile an enema of an ounce of brandy in a pint of warm milk had been given, a jug of hot water put to the feet, and cold applications made to the head. These measures had the effect to increase the force of the pulse. During the day the patient passed his motions and urine in bed. In the evening the patient was found in a semi-unconscious state, with his general condition rather improved; was less drowsy; would make some kind of reply when loudly spoken to; could swallow, and was given milk punch. November 15th, morning, the patient was found to be much better and quite sensible, though unable to call persons or things by their right names; for instance, he said a man standing by was his dear mother, a bunch of keys was a chair, etc. From this time the patient progressed satisfactorily, recovering complete sensibility and correct expression in a few days, and at the end of six weeks from date of accident was considered to have recovered from his injuries, but, owing to sickness in his family, was not discharged from the hospital till December 30th, just two months from the time of admission.

Ophthalmoscopic examination of right eye, made soon after leaving the hospital, revealed the optic disc much swollen, with retinal veins somewhat enlarged, and the arteries but slightly diminished in size. On recent examination the optic disc is still somewhat bulging, its outline well defined, and whitish gray in color. Pupil of right eye movable and of the same size as the left. The sight of the left eye is normal.

The fractured and depressed frontal bone appears to have risen to some extent, so that the depression is not now very marked.

The grasp of the right hand is not quite so powerful as the left, and so is pronation and supination somewhat restricted in the right, but with this exception perfect use of both has been recovered.

COMPLETE OBSTRUCTION OF THE RECTUM BY CANCER RELIEVED.

November 25, 1880. Mrs. E. K., aged thirty-six, residing in the southern part of the State, entered St. John's Hospital with the following history: About two years ago began to be troubled with what her attending physician called bleeding piles, and subsequently more or less with diarrhoea, the last attack of the latter disease occurring two weeks ago. Ten days ago increased pain in defecation and distention led to the calling in of another physician who made a digital examination, and stated that the bowel was obstructed with a fibrous tumor, and advised her to go to some hospital and have it removed by an operation. On admission to St. John's the patient's abdomen was enormously distended, having had, as she said, no movement of the bowels nor passage of wind for eight days. Exploration of the rectum revealed a nodulated cancer (scirrhus) completely encircling and obstructing the intestine, situated about an inch above the anus. The distress and suffering of the patient

being great, it was thought best to make an effort to pass a tube through the stricture; but owing to the nodulated character of the tumor it was found difficult to decide which of the several depressions was the right entrance to the way through the dense mass; the one, however, near the centre seemed the most promising, and after some difficulty a No. 10 catheter was passed, being instantly followed with a prolonged discharge of flatus, with great relief to the patient. Dilatation was continued till the forefinger was passed, and then a rubber tube, somewhat larger, rounded at the end was introduced, a bougie being used as a director, and through the tube two quarts of warm water was injected and retained a while to liquefy the fecal accumulation, and allowed to flow off, being assisted by an exhausting syringe; then more water was injected, and withdrawn again. By this proceeding the intestines were completely relieved of pent-up flatus and fecal matter, and the operation was performed twice while the patient remained in the hospital. Owing to the resiliency of the cancerous stricture, the obstruction of the bowel was found as complete twenty-four hours after dilatation as before, and as a more permanent method of relief the patient was advised to undergo the operation of colotomy, as a good result could be confidently anticipated, and by it life would be prolonged and rendered comparatively comfortable till terminated by the malignant disease; but she refused to submit to any operation which did not include the removal of the cancer. The operation for excision of the cancer, however, was not deemed justifiable on account of the extent of the disease of the rectum and the involved adjacent parts; so the patient left the hospital December 4th, and returned to her home improved in general health and, temporarily, at least, relieved of suffering from obstruction. In this case the symptoms were remarkably insidious and deceptive, so that only a few days before complete obstruction took place was attention directed to the diminished calibre of the bowel, which led to an examination being made. The tendency to diarrhoea and the existence of symptoms referable to hæmorrhoids and dyspepsia probably caused the real nature of the disease to be overlooked during the two years' illness of this woman.

SEVERE CONTUSION, AND FRACTURE OF THE LOWER END OF THE TIBIA AND FIBULA OF LEFT LEG.

October 5, 1880. P. F., aged thirty-eight, while engaged at his work in the Lowell Machine Shop, was struck by a pulley in rapid revolution, falling from a height of ten or fifteen feet, and weighing four or five hundred pounds. The force of the blow was received on the left leg behind the ankle joint, knocking the man down and resting on the limb. The weight was lifted off by fellow-workmen, and the injured man brought to St. John's Hospital. On examination a contusion was seen extending from the heel to a point just above the ankle-joint. The fractured tibia and fibula were reduced and padded, lateral splints applied, and to the contusion a piece of absorbent cotton wet with a solution of carbolic acid 1 to 32 in strength. Considerable tumefaction followed, which subsided in the course of a week, leaving behind the joint a dark discoloration of the integument which sloughed off in the course of two weeks, leaving a healthy granulating surface which rapidly healed, so that at the end of five weeks complete cicatrization of wound and perfect union of both bones had taken place.

MECHANICAL ATRESIA VAGINÆ.

ABOUT two years since I was consulted by a woman, not far from twenty years of age, who had been married six months. She gave me the following history of her case, which became more and more interesting to me as a continued treatment developed all its peculiarities.

Her husband was possessed of strong passions and wished for sexual commerce very frequently. Upon her part each sexual act caused the most intense suffering, and she had come to dread his approaches more and more until for the past few weeks the intolerable anguish which she suffered had led her mate to advise her to consult a physician.

A vaginal examination disclosed the following: The vagina was somewhat elongated, its diameter was less than three fourths of an inch, indeed I was unable to introduce my finger for more than an inch, and the slightest inward pressure caused my patient to cry out from pain the most acute. I discovered, by the means of a small speculum, that a prominent ridge extended the entire length of the vagina upon its anterior surface. This ridge was hard and fixed. The whole vaginal tube seemed to be entirely undilatable, while the lining membrane was in a state of active inflammation, no doubt from forcible congress. I asked her history as to her disease and she said as follows: "When I was about ten years old I went with other girls after berries. In our course we reached a stone fence upon the further side of which there was a fringe of alder stubs, about two feet high, with sharpened extremities. I was the last to get over, my foot slipped, and as I fell one of the sharp sticks entered my vagina, and I fainted from pain and fright; they carried me to the nearest house, called my mother, and one physician after another was called till three of the best in town were with me. They found a piece of splintered and knotty wood in my body and it was more than two hours before they could extract it. It was eight inches long and had passed up the vagina into the cavity of the abdomen between the womb and bladder, lacerating the vagina through its whole extent. I was confined to the house for over two years." The result of this terrible injury was a firm cicatrix upon the anterior wall of the vagina, fastening the tube to the bladder very rigidly. The patient wished to be cured if possible, and indeed I had learned before this stage of the examination that she was well advanced in pregnancy, so an operation was in the highest degree necessary. I called a neighboring physician to aid me in administering ether, and when she was anesthetized I proceeded to operate, and with my knife blade and handle, etc., I at length succeeded in separating the cicatrix from the adjacent tissues, then dilating the tube I packed it carefully and firmly with lint well saturated with antiseptics. I continued this plugging till the wound was well healed and, that too, with no contraction of its normal diameter. I forbade any intercourse till a year after labor, supposing all went well up to that time. Soon after the favorable issue of this treatment I lost sight of my patient.

A year or so after this I received a letter from her in which I was informed that she was the mother of a healthy boy, that the labor was favorable, with no laceration, and then came many expressions of gratitude for her deliverance from so grave a complication.

MANLIUS.

New Instruments.

URETHRAL SYRINGES.

BY EDWARD L. PARKS.

In the number of the JOURNAL for March 3d two separate instruments for the treatment of gonorrhoea are represented by plates and descriptive articles. Neither of them seem to me superior, at least, to a simple instrument which I devised a few years ago and presented at a meeting of the Suffolk District Society.

One of my instruments is now before me, made by Messrs. Leach and Greene, and they promised to sell single ones for seventy-five cents. An ordinary English plastic catheter of 22 F. calibre is cut off at about three inches (less would be better) from the inserting extremity. The cut end is surrounded by a metal flange (simply a perforated disc) and an ivory mouth-piece added. This is to be used with a syringe. Also before me I have what I believe to be the most suitable syringe — one for the eye and ear — a small rubber bulb with a nozzle, but no connecting tube.

The patient is to insert the catheter as far as it will go, and then, filling the bulb as many times as directed, by inserting the nozzle of the syringe in the mouth-piece of the catheter he throws the fluid through the catheter.

In this way a large quantity of fluid can be injected, though the instrument enters the urethra but once, being retained in position. The fluid returning outside the catheter (as experience justifies me in believing it does) unfolds the rugæ of the mucous membrane already evenly distended by it. This is a simple instrument, and if your instrument-maker does not have one he can readily make it. It is easy to select a catheter whose eyelet will not engage the mucous membrane.

Boston, March 9, 1881.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

MARCH 14, 1881. DR. T. B. CURTIS presided.

DIPHTHERIA.

DR. HALL CURTIS reported a case of diphtheria, fatal on the third day from cardio-pulmonary thrombosis and (perhaps) embolism. Vide page 267 of this number of the JOURNAL.

DR. FITZ thought the cause of the rapidly fatal suffocative symptoms was rather to be attributed to cardiac paralysis than to thrombosis or embolism, in the absence of other causes of suffocation. He had made but one post-mortem examination where sudden and unexpected death had occurred as a result of diphtheria. The case was that of a child who had apparently recovered from the immediate effects of the disease, but died while being removed from a carriage after her return from an airing. A general and extensive fatty degeneration of the heart was found.

The sudden termination of cases of diphtheria in the manner reported was not to be regarded as an extremely rare occurrence. One such instance had taken

place under his own observation, the patient dying unexpectedly on the fifth day of the disease with symptoms of asphyxia, while air freely entered the lungs. The literature of the subject contained numerous reports of similar cases.

The diagnosis of cardio-pulmonary thrombosis as a cause of the fatal asphyxia is opposed by the absence of thrombi where post-mortem examinations have been made by thoroughly competent observers appreciative of the suggestion of such possible condition. It is further opposed by the usual condition of the blood in diphtheria, namely, a thin fluid with but little tendency to form firm or voluminous clots.

The mechanism of death would be the same were a paralysis of the heart the immediate cause, while the nutritive changes taking place in this organ, the effects of septicæmia, and the progressive interference with the oxidation of the blood from the pharyngeal obstruction, offer a satisfactory explanation for the occurrence of such a condition.

The question raised by Dr. Reynolds regarding the difficulty of diagnosis in cases of tonsillar and pharyngeal inflammation during epidemics of diphtheria was one of great practical importance. Every physician must have felt himself in frequent doubt at such times, and, although the typical cases were readily classified, there were others whose nature was not made clear by the immediate symptoms. Even the diagnostic importance of albuminuria might be overrated. He recalled the case of a lady, of an extremely nervous temperament, subject to frequent and peculiar vaso-motor disturbances, whom he had treated during two attacks of tonsillar inflammation separated by an interval of a year or more. In both attacks the swollen and congested tonsils were partly coated with a gray and somewhat translucent membrane in which were numerous small flocculent spots. The urine was of a reddish-brown color, resembling diluted coffee, and contained a large quantity of albumen, numerous red blood corpuscles, and frequent blood casts. Not only were similar phenomena present in both attacks, but he was informed that the urine presented a like appearance whenever this patient suffered from sore throat, which was not rarely. Recovery was rapid and complete; the patches showed no tendency to spread, and they disappeared without ulceration of the mucous membrane.

It is well known that cases of apparently simple sore throat may be followed by paralytic sequelæ, and their relation to characteristic cases of diphtheria is such as to indicate the probability of a direct contagion from the latter or the simultaneous action of the same cause.

With such experiences it would seem that at times when diphtheria is epidemic all cases of sore throat should be regarded with suspicion, and should be treated with the view that sooner or later they may give evidence of a diphtheritic nature. At the same time undue fears should not be aroused, as the possibility in any given case often proves to be far removed from certainty.

Dr. CUTLER said that the only case of sudden death following diphtheria he had ever seen occurred rather late in the disease, and seemed to him to be due to the condition of the heart, which was markedly fatty. In a few other cases death was evidently due to septicæmia. In all the cases observed by him there had been few and loose clots in the blood. He had met with no reference to cases of death from embolism in those German authors he had at his command. The diagnosis made

by Dr. Curtis might be the correct one; the symptoms were strongly suggestive of it, and the only other tenable view, cardio-paresis, being apparently negatived by the general condition of the patient and the persistence of a good pulse till the last. He would not care, however, to make a positive diagnosis himself without an autopsy.

Dr. T. B. CURTIS said that as he had seen the case reported by Dr. Hall Curtis in conjunction with him, and had been present at the death of the patient, he would take the liberty of adding a few remarks:—

The case was, as far as his knowledge went, quite without precedent, on account of the precocity of the supervention, in the third day of diphtheria, of sudden and rapidly fatal symptoms, which consisted in asphyxia with unobstructed air-passages, and which seemed to him to be significant of, and only explainable by, cardio-pulmonary thrombosis and perhaps embolism. Owing to the relative simplicity of the conditions obtaining at the time of death in this case, and growing out of the early period at which the fatal disturbances occurred and the consequent absence of almost all complications,—there being no very marked evidence of malignancy or signs of general poisoning, few if any signs of asthenia, no implication even in the slightest degree of the air-passages or lungs, no cough, no impairment whatever of the voice; and, moreover, the period at which fatty degeneration and paralysis of the heart are usually observed being still quite remote,—taking into consideration all these facts, the case, even without an autopsy, which could not be obtained, seemed to afford evidence of the real existence of cardio-pulmonary thrombosis as a possible occasional complication of diphtheria.

The physicians in attendance were immediately struck, while witnessing the short death-struggle, by the absolute similarity of the phenomena observed to the symptoms which have been so often seen in lying-in women, in cases of puerperal thrombosis and embolism, as described by obstetrical practitioners. The speaker himself one night, when on duty as *interne* at the Hotel Dieu of Paris, witnessed the same sudden, terrible, and rapidly fatal asphyxia with open air tubes and unobstructed respiratory movements, in a recently confined woman.

In the entire absence of respiratory obstruction to account for the sudden asphyxia, the only other supposable agencies to be taken into account as possible causes of sudden death in this case are the cardiac complications of diphtheria, which are liable to incapacitate the heart from fulfilling its functions, and to cause death, more or less suddenly, by *syncope*. These causes of heart failure are fatty degeneration of the cardiac muscular fibres and paralysis of the heart.

Fatty degeneration or steatosis, probably resulting from myocarditis, is found once in every five cases of fatal diphtheria, according to Sanné. This lesion is common enough in many other diseases besides diphtheria, and often exists without any obvious disturbances of circulation. The symptoms attributed to it consist mainly in weakness and slowness of pulse accompanied by fainting fits, culminating in a more or less gradual, and occasionally sudden, fatal termination by *syncope*. It is mostly observed in cases which have lasted from ten to twenty-one days, in which convalescence has apparently been reached; in only one case, according to Sanné, has this alteration of the heart been found as early as the sixth day.

The *neuromparalytic* cardiac complication is asserted by Sanné to be the only acceptable cause and explanation of the puzzling sudden death occasionally observed in diphtheria. Paralysis of the heart, like the other paralytic sequelæ of diphtheria, usually comes on rather late in the disease, or after the disease. It represents, according to Sanné, the last phase of the extension of the neuromparalytic complications. These set in mostly during convalescence, from one to two weeks, or even longer, after the apparent recovery of the patient. The symptoms attending the implication of the cardiac innervation consist in slowness, often extreme, of the pulse, the latter being at the same time small, thready, and irregular. There is sometimes a moderate degree of dyspnoea, dependent upon the failure of the circulation; but the most conspicuous and significant symptom consists in a syncopal state, which becomes gradually more and more pronounced, and eventuates in death by *syncope*, without any marked respiratory struggle.

In the case reported by Dr. Hall Curtis, on the contrary, the conditions observed before and during the death struggle were very different from those just described. The pulse was fairly strong, regular, at 104; there was no evidence of asthenia, no faintness, no signs whatever of a syncopal tendency even. The death struggle, sudden and brief, was that of *asphyxia with open air tubes*, the patient making frantic efforts at aeration, gasping with open mouth, and, lastly, the heart was the *ultimum moriens*. This last fact, which was distinctly and unequivocally verified by both the physicians present after all respiratory movements had ceased, and the body and limbs, previously convulsed, had become relaxed, sufficed in their minds to negative the possibility of either of the cardiac complications of diphtheria, degenerative or neuromparalytic, which cause death more or less suddenly by *syncope*.

With regard to the fluid, syrupy condition of the blood, known to be so commonly found *post mortem* in cases of fatal diphtheria, it is evidently not the rule since so many exceptions have been recorded.

The question of the diagnosis of diphtheria in certain ill-marked, incipient, mild, or imperfectly developed cases, has been brought up. Evidently in many such cases the diagnosis cannot but be very obscure and, for a while, doubtful. The differences in the habits of diagnosis of physicians are, however, quite as great as those of the various types of disease. Practitioners may be broadly divided into two categories. Some physicians seem to meet with very few if any cases of simple "sore throat," especially at times when diphtheria is prevalent. On the other hand, they have, in their practice, a surprising number of cases of diphtheria, counting them by hundreds; moreover, it is observed that their therapeutic results are remarkably satisfactory, and that they have and express great faith in their methods of treatment, whether by chloride of potassium, forced stimulation, or potato poultices. The case of a young lady was recalled who was kept in bed for a number of days and isolated on account of an alleged "diphtheritic throat," while daily bulletins of her progress were being issued to a large circle of anxious friends; all the while she was steadily gaining weight, and her convalescence was short and rapid. The treatment in this case was remarkably efficient. The other category of practitioners comprises those who have in their practice comparatively few cases of diphtheria; who experience high rates of mortality

among them, and are extremely skeptical with regard to the real efficiency of medicinal treatment in such cases. Physicians of this class, on the other hand, see and treat successfully many cases of tonsillitis of various kinds, and also many cases of faucial angina, catarrhal or herpetic. Evidently the nosological term diphtheria is not always used with one and the same signification.

DR. GEORGE B. SHATTUCK referred to Guttman's experience with the muriate of pilocarpin in diphtheria, as published in the *Berlin klin. Wochenschr.* (No. 40, 1880), and asked whether this treatment of diphtheria had been tried by any gentlemen present. Dr. Vogel reported several cases lately in the *JOURNAL*. Dr. Guttman reported extremely favorable results, and had not encountered the ordinary depressing effects of this drug, or where such threatened to manifest themselves they were readily counteracted by small but repeated doses of stimulants.

DR. LANGMAID reported the case of a lady whom he was called to see with symptoms of swelling and some pain in the throat, but no fever. On examination he found a white membrane hanging down behind the soft palate, and on using the mirror he discovered that the whole surface of the right posterior nasal fossa was covered with a membrane which could not be detached by traction, and could not have been discovered without rhinoscopic examination, as it was localized there, not being present elsewhere. Simple syringing with permanganate of potash was employed and the whole thing disappeared in three days. He supposed that it was a diphtheritic membrane.

Recent Literature.

Diagrams of the Nerves of the Human Body. By WILLIAM HENRY FLOWER, F. R. S. Third Edition. Philadelphia: Presley Blakiston. 1881.

The reputation of Flower's Diagrams is so well established that we have little to do beyond welcoming a new edition of them. They are so clear, thorough, and well executed that their popularity is easily accounted for. We regret that in this edition Mr. Flower has not so modified the plan of the digital nerves as to show the dorsal offshoots from the palmar branches running towards the ends of the fingers. We could wish that the motor root of the submaxillary ganglion were more distinctly to be traced to the chorda tympani. Similar points for criticism might, no doubt, be found, but for the work as a whole we have nothing but praise.

T. D.

— A pharmacist was prosecuted recently in Paris for having caused the death of a girl by selling powdered oxalic acid in place of powdered Rochelle salt. He, in defense, stated that he sold what his wholesale druggist had furnished him with, and upon whom, therefore, the responsibility ought to rest, seeing that the substances in powder are not distinguishable by the eye or touch. The court, however, disallowed this plea, on the ground that every pharmacist, by virtue of the monopoly he enjoys, is strictly held to the duty of verifying every medicine which he offers for sale. He was condemned to a month's imprisonment, a fine of one thousand francs, and two thousand francs damages, payable to the father of the deceased girl.

Medical and Surgical Journal.

THURSDAY, MARCH 24, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

CONFLAGRATIONS IN INSANE HOSPITALS.

THE recent terrible fires in insane hospitals have so startled us in our fancied security that we are now led to ask, Are any such buildings strictly fire-proof? Glancing hastily back at the record of the past twenty-five years we find that there have been two fires at the Vermont Asylum; one at the New York State Lunatic Asylum at Utica, and one at the Kansas State Asylum, which, however, destroyed only a tolerably small portion of each of these institutions. But we find that the Ohio State Lunatic Asylum, the West Kentucky Lunatic Asylum, the Minnesota State Lunatic Asylum, and the State Lunatic Asylum at Danville, Penn., have been almost totally destroyed and a considerable number of lives lost. That more lives have not been lost may be considered almost providential; as, for instance, at Danville, where the patients were in the chapel, and consequently in a body, and easy to control. The money loss, too, though of trifling importance compared with the sacrifice of life, has been so great as to entail a heavy burden on the tax-payers. It may be safely asserted that the loss at the asylums, almost totally consumed, must have reached to two and one half millions.

We are aware that conscientious efforts have been made to render recent insane hospitals fire-proof, and we should say, from a casual inspection of the State hospitals at Morristown, N. J., and Middletown, Conn., that they might be classed as fire-proof; but can we say as much for our Massachusetts hospitals? The older institutions at Worcester, Northampton, and Taunton were fairly well up to the times at which they were built, and additions have, at various times, been made to their means of protection. In the new portion of the Taunton Hospital stairways are of iron, the party walls are numerous and well carried up. We find, also, from the last annual report, that the attic, which was continuous throughout the whole length of the building, has been divided by brick walls into twelve sections, which would have the effect of impeding or preventing the spread of fire, and, furthermore, connections have been made with the city water works, largely increasing the water supply. All of these old hospitals — especially Northampton — are well supplied with water, which is a very important fact when we remember that some of these fires are dependent for their extent on scarcity of water. These hospitals are, two of them, near large cities and one near a large town, which makes it possible to call

in outside aid with sufficient promptness to be of some service.

Turning to the recently erected hospitals at Worcester and Danvers, we find the former substantially built, attention having been given to protection from fire, and as a further safeguard hydrants and extra pipes are about to be put in (it must be remembered that this hospital is near a large city). At Danvers, unfortunately, the building is not so well built, or provided with fire-saving apparatus, and we find the trustees referring in each of their annual reports to their exposure to fire. In 1879 they asked the legislature for an appropriation for fire apparatus, and were given nine thousand dollars. They say, in their report for 1880, that that sum is not enough, but when expended the hospital will be partly protected. We understand that ladders for outside use have been made; that "automatic sprinklers" have been put in, and that full pressure can now be applied to the extra pipes for use in case of fire without fear of bursting, which was not the case before. All the arrangements will not be finished for some time, as a contractor is six months behind time.¹

Beside the inevitable modifications in structure which must be made in non-fire-proof buildings, there are certain precautions, which should be adopted at all large institutions, for the purpose of effective action when a fire breaks out. There should be, for instance, a well-drilled fire corps made up from the employees. Though the medical officers and attendants should have a knowledge of the use of the fire apparatus, in case the fire becomes at all general, their combined efforts will be required in controlling and managing the patients, who become so much excited at the sight of fire. At the Danville fire, the attendants, it is said, could do nothing but look after the patients. The various other employees, as the clerks, engineers, farmers, farm hands, cooks, etc., must be looked to to do the main portion of the work. There should be frequent and systematic drills of such a corps, and trials of the apparatus, and every employee, male and female, should have a place assigned him, and be ready to take it at a moment's notice. There should be entrances from both ends of all wards, outside fire-escapes, gratings in the windows that could be unlocked, ropes, axes, pails of water, and fire-extinguishers easy of access. At a hospital like that at Danvers, exposed on the top of a high, barren hill, and remote from even a small town, the outside fire service should be especially large. That is, there should be a good-sized hand-engine and two or more hose wagons ready for any emergency.

It is not easy to say what general measures ought to be taken, but perhaps it would be well to provide in some way for a State fire inspector, who should make frequent visits to the State institutions, and carefully examine into the construction of the buildings and the means of protection provided against fire. He should personally test the apparatus, and be present at or superintend drills of the fire companies, and in all ways

¹ About March 14th the legislature passed a resolve giving Danvers three thousand dollars to complete the fire apparatus, and specifying that this apparatus should be completed within ninety days.

satisfy himself that nothing was left undone. The expense of employing a competent person would involve a small additional outlay of money on the part of the State, but when we remember how much loss of both life and money can be saved by early, efficient, and continuous action in the event of a fire, it becomes our duty as citizens to consider any means which will afford a surer protection than we now possess.

TRICHINÆ AND CHOLERA IN THEIR RELATIONS TO THE AMERICAN PIG, AS NOTED BY CONSUL CRUMP.

VICE-CONSUL CRUMP, of Philadelphia, having produced a porcine panic in the English newspapers, from the *Times* downwards, by his picturesque and imaginative description of hog-cholera and trichinosis; and several of the continental countries, notably France and Austria, having prohibited the importation of American pork products, any additional light upon the viability of trichinæ is desirable. The *Lancet* gives an abstract of a late discussion of this subject at the Académie de Médecine (February 22d), and we are glad to see that the general opinion expressed was of a character somewhat reassuring to a great American industry, which between shrewd schemes of speculators and the stupid fears of consumers has had a hard time lately. Consul Crump will be relieved to know that even the most timid and cautious members of the French academy would not hesitate to use American lard, and according to most of the experiments referred to there is really no reason why he himself should not occasionally enjoy a little roast pork. It is really marvelous that with so many perils from pork on all sides of us in this pig-raising country we not only escape being all of us the constant victims of the effects of hog cholera, and tenements at their will of colonies of trichinæ, but, what is still more extraordinary, that evident cases of trichinosis should be so rare as to be gladly welcomed by the instructor when presenting themselves in our medical clinics. We have before us at the present moment a clinical lecture by Professor Da Costa, delivered to his class only two months since at the Pennsylvania Hospital, on Acute Trichiniasis, Marked by Continuous Fever and Severe Muscular Symptoms, and illustrated by a case, which begins as follows: "The case now before you is a striking one from more than one point of view. It presents a typical illustration of a disease which I have rarely had the opportunity of presenting before the class. It is instructive in the accuracy of which the diagnosis admits," etc. Again, Dr. Rauch, of the Illinois State Board of Health, informs us that there have been only twelve known deaths from trichinosis in the last ten years in that State.

It is evident that either the dangers of eating American pork products exist mainly in the minds of designing speculators and misguided consuls, or else that the American pork-packer is possessed of machinery for selecting all diseased animals for foreign export, but little, if at all, inferior in swift accuracy

and reliability to the ingenious apparatus used in the primary process of slaying and dressing the generic pig. It would seem as if the countries of Europe occupied toward us somewhat the same relation as that which his pastor bore to the Swiss peasant. It was this peasant's habit when he killed a pig to send as a present a selected piece to his good pastor, and if no bad results succeeded the pastor's indulgence he then eat the rest himself. Only our experiment *in corpore vili* is less satisfactory, for in the case of Europe it is difficult to distinguish between illness and pure fright.

We hope the opinions expressed by Messrs. Colin, Davaine, and Vallin were not unconsciously influenced by the fact that the meeting of the Academy took place on the anniversary of the birthday of the Father of this country, but as their remarks were mainly confined to the relation of the results of experiment and observation we think ourselves justified in leaving out of account any such perturbing influence.

The following is the *Lancet's* abstract of the meeting of the French Academy, to which are added some remarks of its own:—

The meeting of the Académie de Médecine of February 22d was devoted to the discussion of the viability of trichinæ, and opinions were expressed of a more reassuring character than those to which attention was called last week. M. Colin, of Alfort, has investigated the extent to which the process of salting renders meat innocuous, and he concluded from a number of experiments that the salting always finally destroys the trichinæ, but that it is impossible to determine the lapse of time necessary, and the danger from such food is greater the shorter the time since the salting. He also investigated the question of what amount of cooking is requisite to insure destruction. Boiling he found to be effective provided it is maintained for a considerable time, which varies in its necessary length according to the size of the pieces of meat. Roasting only killed the trichinæ when it had been carried beyond the point common for mutton or beef. Quick roasting or boiling, leaving the central parts of the meat red, was quite insufficient. He expressed the opinion that many cases of gastric and intestinal disturbance are the indications of slight trichinization. M. Davaine, however, mentioned that as low a temperature as 56° C. (134° F.) is sufficient to destroy them, and that in estimating the amount of time needed to cook a joint, thirty to thirty-six minutes should be allowed for each half kilogramme. The same question was considered also by M. Vallin, the results of whose experiments agreed with the statements of M. Davaine. He found that it was necessary that joints of less than six kilogrammes should be cooked for four hours, and that for larger joints boiling for at least five hours was required. The effect of salt in preventing the decolorization renders the tint, he thinks, an uncertain indication of the sufficiency or insufficiency of the cooking. M. Chatin maintained that salting does not necessarily kill trichinæ. Infested meat was preserved in salt and then given to guinea-pigs, and in several of the animals trichinæ in process of development were found. Moreover, in meat which had been heated to 111° F. the trichinæ were found perfectly mobile.

In spite of the doubt as to the exact temperature at which trichinæ die, and the uncertainty as to the efficacy of ordinary cooking for their destruction, there is a general disposition to rely upon the fact that trichinosis in man is a very rare disease, in spite of the importation of diseased pork. Mr. Mundella lately stated in the House of Commons that our importation is twelve times as great as that of France; and it is reasonable to conclude, therefore, that twelve times as many trichinæ come to us as come to France from America. What is their actual number cannot, of course be known, but it may be remembered that a single outlet has been found to contain a hundred thousand worms. The fact that no outbreaks have occurred in this country is probably to be ascribed not only to the influence of cooking, but to the process of salting, which, as just stated, if efficiently performed, seems to kill the parasite. Mr. Mundella intends to wait for an outbreak of trichinosis before following the example of the French government, and prohibiting the importation of American pork, and the Belgian government have formed a similar resolution. It would be more satisfactory to know that some measures were taken, by systematic examina-

tion of samples of the meat, to ascertain the reality of the danger to this country, for it must not be forgotten that outbreaks and deaths have occurred here in past years.

The disinterested testimony of the French Academy, the general immunity of our native population from contamination, and the energetic diplomacy of our Secretary of State, offer grounds for hope that the respectability of the American pig may soon be vindicated. In the mean time we shall continue, without a shudder, to offer the accustomed hospitality of our table to the spare rib, the broiled bacon, and the various products of the gridiron or frying-pan, leaving raw meat, whether fresh, salted, or smoked, to those who like it, and even they, we are inclined to think, may indulge their taste with considerable impunity when resisting the temptation to buy at half price.

MEDICAL NOTES.

— There is a man in Boston who thinks that the Board of Health of that city is a nuisance, and he has published a small pamphlet to that effect. He begins his indictment as follows: "They spend a very large amount of the people's money—about sixty-three thousand dollars the last year—and have spent a much larger amount some years. They send out twenty-five thousand or thirty thousand notices a year, keep the owners of real estate constantly annoyed, and cause them unnecessary expense. They act as auxiliaries to worthless tenants. If one is warned out for non-payment of rent, or wishes to move and injure the owner or damage his property, he goes to the Board of Health and complains that the house is damp or smells bad, and the board immediately orders the owner to abate the nuisance."

It seems evident that this is written by the owner of some of the poorer class of tenements, who has been compelled by the board to remedy the worst of the defects in his houses, so that they shall not threaten the health and life of his tenants and of the neighborhood. The wrath of such landlords at having their profits interfered with is common enough, but they very rarely rush into print with their grievances, and hence this wail of "Common Sense," as he signs himself, is quite a curiosity. — *Sanitary Engineer.*

— Mr. Holden in his recent Hunterian oration told the following story, which illustrates the state of anatomy in Europe before the reformation brought about by Vesalius and Fallopius. The physicians in attendance on the Margrave of Baden Durlach disputed among themselves as to the position of his heart in his thorax, one of them contending with Galen that it lay in the middle, the rest being bold enough to affirm that it was on his left side. As this unfortunate doubt assumed the aspect of a serious practical difficulty, when it came to determining the precise spot on which should be applied the plaster which was destined to relieve the sufferings of the Margrave, it was decided to appeal to nature. A pig was therefore brought into the royal chamber, and opened in the presence of the sick man. The position of the heart was demonstrated to him: if

in a pig, therefore in a prince.* His highness gave way before this argument, and the plaster was placed accordingly; while the physician, who still had the temerity to defend himself by drawing an anatomical distinction between man and pig, was dismissed from the court.

NEW YORK.

— The fortieth annual commencement of the medical department of the University of the City of New York was held at the Academy of Music on Thursday evening, March 8th, when the degree of M. D. was conferred upon 199 graduates. The Mott gold medal (for the best anatomical preparation) was awarded to S. C. Blaisdell; the first faculty prize (of \$500 for general scholastic standing) to Frank M. Donahue; and the second faculty prize (of \$500, for the best competitive examination in the same general departments) to Milton B. Titus. Joseph Clark Thomson was the valedictorian, and the address to the graduating class was made by the Rev. Henry W. Bellows, D. D.

— The twentieth annual commencement of the Bellevue Hospital Medical College was held at the same place on Thursday afternoon, March 10th, and this year the address to the graduates was made by one of the professors, which is rather an unusual thing at the commencements of the New York schools, although it is the rule in Philadelphia. Professor Austin Flint, Sr., was the orator, and the subject which he selected was American Medicine. His object, he said, was not to pronounce a eulogium upon the profession in this country, but simply to reply to certain animadversions which from time to time had been made upon American medical men and medical teaching by our own medical journals. Among the arguments that he advanced were the following: The papers of American writers were fully appreciated abroad, and American students were treated with great respect in European universities. It was often claimed that the profession was overcrowded; but the general law was the same in medicine as in other professions and walks of life,—the supply was regulated by the demand, and not only in quantity but also in quality. It would not be denied that those who have been graduated from a regular school were better qualified to practice medicine than those who had not had the same advantages; but if too many restrictions were placed upon our students the tendency would be to drive them into the irregular schools, since there was in this country so large a field for medical practitioners. Again, it was sometimes said that the only object of the great mass of those who studied medicine was to obtain the legal right to practice in the shortest and easiest manner possible; but this was disproved by the fact that such large numbers of students came from long distances, at great personal inconvenience, to the large cities, notwithstanding the outlay of money required, on account of the superior advantages to be obtained in the great medical centres, instead of studying at schools nearer home, where the expenses were often merely nominal and the requirements for graduation corre-

spondingly few. Many of them, indeed, came from States where it was not necessary to have any sort of a diploma whatever in order to pursue the practice of medicine. There were 118 graduates, and the valedictory address was delivered by Charles E. Nammach, of New York.

The annual dinner of the Alumni Association of the Bellevue school was held in the evening at Nils-son Hall, adjoining the Academy of Music, when addresses were made by Dr. Isaac E. Taylor, president of the college, J. Taber Johnson, of Washington, the retiring president of the Association, and Drs. Goffe and Carlisle, of the graduating class. Professor James R. Wood spoke for the faculty, the Hon. John R. Brady for the trustees, and Dr. Gaspar Griswold for the alumni of the college. Among the other toasts responded to were, The Commissioners of Charities and Correction by Commissioner Brennan, Our Sister Alumni Associations by Dr. R. F. Wier, of the College of Physicians and Surgeons, and Dr. D. B. St. John Roosa, of the University, The Bench by Chief Justice George Shea, and The Medical Press by Dr. P. F. Mundé, editor of the *American Journal of Obstetrics*.

— Dr. John Dennison Russ, a well-known philanthropist, has just died at his home in Pompton, New Jersey, in the eightieth year of his age. He was born at Essex, Massachusetts, and was graduated at Yale College in 1823, after which he studied medicine at Bowdoin College. After spending some further time in study in Baltimore and in Boston, he took charge of an expedition sent out from the latter city in 1827 to render assistance to the suffering patriots of the Greek Revolution, and established a hospital at Paros, which he superintended for fifteen months. Later he came to New York, and in 1832 began to turn his attention to the education of the blind, a cause in which he did special service by making many improvements in the methods of printing for the blind. At the time of his death he was also connected with the New York Juvenile Asylum and the Prison Association.

— On the 12th of March a small-pox patient at the Riverside Hospital on Blackwell's Island, thirty-seven years of age, committed suicide, while in a state of delirium, by throwing himself into the East River. The man had only been admitted the day previously, and was placed in one of the rooms opening out upon a balcony inclosed with a stout iron railing. By accident one of the doors in this railing had been left unlocked, and he rushed out upon the neighboring dock, from which he plunged into the water. One of the female nurses attempted to intercept his escape, but was quickly knocked down by him.

— Mr. George Seney, of Brooklyn, has given \$200,000 and a site worth \$70,000, in addition to several other valuable lots, for the purpose of erecting and maintaining a new hospital in that city, and a board of thirty-two trustees, including a number of prominent citizens, has just been organized for the institution.

— The twenty-seventh annual meeting of the Nursery and Child's Hospital was held March 11th

when the secretary reported that the number of persons cared for during the year was 2044. — 969 in the city nursery and 1075 in the country branch on Staten Island.

— In consequence of the need for more efficient quarantine arrangements, the proceeds of the charity ball this year will be devoted to that purpose.

— In the ninth annual report of the Roosevelt Hospital, just issued, it is stated that 1171 patients were treated during the past year, and that there were 155 remaining in the institution on the 31st of December. The death-rate was 14½ per cent., and the total expenses of the hospital during the year were \$56,429.91, or an average daily per capita cost of \$1.11.

— A cremation society has been organized in New York, and Rev. J. D. Bengliiss elected its first president. Among its rules are that one half the dues received from active members and all the dues from associated members are to be devoted to an "incineration fund," the purpose of which is to provide facilities for carrying into operation the cremation of deceased members of the society. This is not to include the cost of conveyance of the body to the crematory, but "only the cremation of the body and the return of the ashes" to the friends or relatives. All active members who may have paid in \$10 to the treasury of the society during life, and who may be in good standing at the time of death, will be entitled to this privilege. The annual dues of active members are to be three dollars, with an initiation fee of the same amount.

— A "convalescents' home," for the reception of patients who have been discharged from the different hospitals in the city, but have not as yet recovered sufficient strength to return to their usual avocations, has been in operation for a year, and has cared for forty-seven such cases. The present building is exclusively for females, and it is proposed to procure one for male patients also as soon as the necessary funds have been raised.

— On Tuesday evening, March 1st, the first annual dinner of the "Union of the Titans" came off at Delmonico's, and was an occasion of much festivity. This is a newly-organized club, the first requisite for membership in which is that the applicant shall be at least six feet and two inches in height. The tallest of the "Titans" is six feet six inches, and among the members are Dr. William A. Hammond and Dr. A. E. MacDonald, superintendent of the insane asylum on Ward's Island.

— At the last meeting of the Academy of Medicine a paper on Statical Electro-Therapeutics, or Treatment of Disease by Franklinism, was read by Dr. William J. Morton. Some of the results which he claimed for this form of electricity were, to say the least, very striking, as, for instance, the complete cure (?) of a patient suffering from progressive locomotor ataxia by seven applications. The case was said to be a well-marked one of the disease, and although a considerable time has elapsed since the treatment was discontinued, there has been no return whatever of any of the symptoms.

— On or about the 22d of February a child weighing 21½ pounds was born in Brooklyn, and in honor of the Father of his country it was given the name of George Washington, in addition to two or three others, which were probably thought to be demanded by its unusually large size.

Miscellany.

LETTER FROM PHILADELPHIA.

MR. EDITOR,— Commencement week has come and departed, and although the exercises of the great medical schools cause scarcely a ripple in the life current of such a large city as this, yet the advent of three hundred and odd full-fledged physicians may be considered, in medical circles at least, as of some importance. These brand-new M. D's., with the twenty-five or twenty-eight hundred others graduated this spring in the medical institutions of this highly favored land, are of course urgently required to supply the great need (!) for more physicians that is felt in all our great cities. It will be an interesting question to decide at some future time, when the profession becomes quite full (for there is such a thing as overcrowding even an omnibus), what is to become of those who, after struggling in vain for a foot-hold, finally decide to give up the regular conveyance. Unfortunately, temptations to irregular and disreputable practices are always at hand: specialist may adopt the tricks of charlatan; physician become patent-medicine proprietor, or open a provident dispensary (provident as regards himself), or indulge in venal or criminal practices calculated to bring reproach upon the whole profession. New medical schools are being instituted every year, and the old ones may be counted upon for their quota of graduates, so that whatever misfortune may be in store for our country we need not fear a doctor-famine, unless, indeed, it be of the kind where the doctors themselves are to be chief mourners. Under proper conditions cream will rise to the top, but if the movement be too vigorous fermentation, acidity and general disappointment may be naturally expected. (The force of this observation lies in its application.)

The commencement of the Jefferson College was held on the 12th instant, the valedictory being delivered by Prof. Roberts Bartholow, and, as might be anticipated, it was a model essay, appropriate, able, and brief. The graduating class numbered 205; and the usual prizes were awarded. The president of the board of trustees conferred the honorary degree of Doctor of Laws upon J. Marion Sims, of New York, a distinguished alumnus of the school. At the commencement of the University of Pennsylvania (being the 115th annual session), held on the 15th instant, Prof. H. C. Wood, Jr., delivered the valedictory. The class (including 17 dental graduates) numbered 162. The exercises of both institutions were held at the Academy of Music at noon, with the usual musical and floral accompaniments.

The Alumni Association of the Jefferson Medical College held its annual meeting on the day before the commencement. The oration was delivered by Dr. Hamilton Osgood, of Boston, before a large and appreciative audience of ladies and gentlemen assembled in the amphitheatre of the new hospital building of the college. The subject of the address was *The Need of a Radical Change in the Education and Training of*

the American Girl, and the Physician's Duty Therein, and its delivery was listened to with marked attention, and with evident effect. On the same evening the Alumni Association gave a supper at Augustin's in honor of the orator, at which about forty gentlemen sat down, Professor Gross presiding, which passed off in a most agreeable manner. During his stay in the city Dr. Osgood was the guest of Dr. Keen; besides numerous invitations a reception was given in his honor by Dr. George C. Harlan, and he was warmly welcomed by his many friends.

The Philadelphia Board of Health has adopted and ordered to be published the following resolutions, which are similar in purport to those recently passed by the County Medical Society:—

"Resolved, That the Board reiterates its deliberate and positive conviction that vaccination and revaccination are the only sure and reliable means of preventing small-pox, and that, if universally practiced, this disease will speedily cease to exist. Citizens are, therefore, earnestly urged to have the operation performed without delay.

"Resolved, That the medical profession be requested to use every effort to cooperate with the Board of Health in securing the adoption of this important sanitary and preventive measure."

The small pox epidemic still continues, although its course is a quiet one, and its prevalence is not sufficiently great to excite popular alarm. The physician at the Municipal Hospital reports a decided reduction in the patients under treatment; but the number of deaths reported each week has not greatly declined.

The State Insane Asylum near Danville was lately destroyed by fire, although considered fire-proof; it burned steadily, but slowly, until fourteen of the twenty-two wards, with the central building, were consumed. No accidents to the inmates are reported. The loss amounts to about four hundred and fifty thousand dollars. It will be, probably, rebuilt.

The Dauphin County Medical Society held a special meeting for the discussion of medical subjects at Harrisburg on February 10th. It was the largest meeting of the kind ever held in that section, 118 names being signed to the register. A number of practical papers were read, notably those of Dr. S. Weir Mitchell on *The Mimicry of Disease*; by J. L. Ziegler, of Mt. Joy, on *Medical Education in its Relation to Quackery*; and one by Dr. S. B. Kieller on *Some Diseases Peculiar to Men and Boys*; Dr. John T. Carpenter, president of the State Medical Society, gave some *Practical Observations in Using Chloroform*; and Dr. Kerr, of York, read a paper on *Embolism*. A supper at the Loehel Hotel concluded the exercises, which were much enjoyed by those in attendance upon the meeting.

Two cases of medico-legal interest of recent occurrence seem worthy of mention: A young, unmarried girl, about twenty-one years of age, had occupied a room in a boarding-house for a short time, when, early one morning the inmates were shocked by finding a newly-born child in the yard, where it had evidently been thrown from her window. It was upon investigation found that she had been confined without any friendly aid, and, although she denied all knowledge of the child at the time, yet it was evident that, after the ordeal was over, she had taken the child and, in a moment of frenzy, had thrown it where it could not fail to bring upon her almost immediate detection, as,

indeed, it did. The coroner's jury held her to answer the charge of murder, for which she is now awaiting trial. The second case was one in which a little boy, three years old, was left in charge of his infant brother, a red-hot stove being in the room. The mother returned in a few moments, and found the boy brandishing a red-hot poker, with which he had marked the baby's face and then thrust it into the infant's mouth to stop its crying; it is needless to add that the baby died.

In my last letter I spoke of a new medical school now organizing; were it not a little premature I could now give the names of most of the faculty and the location of the building, which has been used for another purpose until lately. From the character of the enterprise, it will not be likely to be a dangerous rival to any of the existing schools; probably, if the fees are low enough and requirements for graduation not too high, it may succeed in this city. In my next letter I hope to give an authoritative announcement upon the subject.

In view of the multiplication of schools and specialties in surgery, I communicate the following circular, which has lately been distributed here. It refers to a proposed offshoot from a dental college, and, as you see, offers unprecedented advantages.

THE MANAYUNK ODONTALGIACAL COLLEGE AND HOSPITAL OF UMBILICAL SURGERY.

SPRING ANNOUNCEMENT.—In order to increase the facilities for obtaining diplomas, the Faculty of this College assumes to matriculate students by MAIL, TELEGRAPH, or TELEPHONE.

MAIL.—Arrangements have been perfected through which the ridiculous formality of attendance upon the courses of instruction may be entirely dispensed with. The Faculty assumes to direct the reading of the matriculate from time of birth. Names may be entered by MAIL.

TELEGRAPH.—Telegraphic communications will be established with the home of each matriculate in any part of the world. Attendance upon lectures may be conducted by telegraph. Highly interesting, important, amusing, and diversified clinical lectures on Umbilical Surgery and allied anal diseases will be furnished by telegraph to all parts of the world. The anatomico-physiologic-histologic-pathological expressions of each disease will be lucidly formulated, and the harmonistic correlation completely established in the umbilical mansion, which is thus constructed, and which will give safe refuge to the practitioner.

PHONOGRAPH.—Theses may be deposited and recorded in the phonograph.

TELEPHONE.—Final examinations will begin at the beginning of each session, and will be conducted by telephone. The very worthy, and highly honorable, degree of D. U. S. and D. P. will be conferred by telephone. The candidate is expected to bow to the Honorable President of the Honorable Board of Trustees and Honorable Faculty as he approaches the diaphragm of the telephone and receives the degree.

B. Low, D. U. S. and D. P., *Dean*.

The full force of this can be appreciated only by the initiated.

VACCINATION AND REVACCINATION.

MR. EDITOR.—There has been a good deal said pro and con of late in the JOURNAL on the subject of vaccination and revaccination. We do not propose to enter into the controversy going on between other parties, but wish to state a few plain propositions relative to the subject, and in regard to what the people ought to be taught by the profession.

First. There is inherent in the human system an element-principle or humor, which, so far as we know, has never been christened, for which we propose the

name of variolum, and is that upon which the small-pox poison acts, and is usually eliminated or neutralized by one attack of small-pox. This, we think, is a plain, self-evident proposition.

Second. Vaccine virus acts upon the same element, and when well and efficiently applied eradicates it or neutralizes it. This we also regard as a self-evident proposition. If it were not, then would vaccination be of very questionable utility.

Third. Vaccination gives immunity from small-pox precisely in the proportion that it eliminates the variolum from the system. This is very clearly proven by the facts that a person once vaccinated has a very decided immunity against small-pox over those not vaccinated at all, and those vaccinated twice or more have even a better protection than those vaccinated once.

Fourth. The liability to small-pox differs greatly in different individuals, and we have good reason to believe that it differs greatly in the same individual at different times. During epidemics of small-pox the facilities for contagion seem to be very much enhanced by the epidemic influence prevailing, and the facility with which the vaccine virus takes at such times seems to be correspondingly enhanced.

Fifth. In an attack of small-pox you may have ten, a hundred, or a thousand pustules, all of which seem to be necessary to the elimination of the variolum from the system. Could you reasonably expect a single vaccine pustule to be equally efficacious in eliminating these very varying quantities of variolum from the system? Do you think that a single vaccine pustule would be as efficacious in protecting the individual who may have a thousand small-pox vesicles as it would be in the individual who is liable to only ten? Then will it not require much more thoroughness for vaccinating in the one of the cases supposed, so as to give complete immunity against small-pox, than in the other? But can we, by looking at a patient, tell whether he is liable to have a few scattering vesicles, or confluent small-pox? Certainly not. Can we find out? Yes. How? By trial. No one need ever make any mistake in this matter, and may always be qualified to perform his whole duty to his patient. Vaccinate him thoroughly. Not a single little puncture in the left arm, but a half dozen or more, say three in each arm. Eliminate as much of the variolum from the system at the first vaccination as possible. What then? Vaccinate him again, and do it thoroughly. What then? Revaccinate him, and thus continue to vaccinate and revaccinate until he is thoroughly vaccinated, if you will allow me the expression, or till all the variolum, be it much or little, is entirely eradicated from the system,—until you find your vaccine virus will no longer take, but will act as if you put it in the arm of one who has had the small-pox. Then you will feel your conscience clear in having performed your whole duty to your patient. Then, and not till then, can you assure him that you have done all that can be done, and have given him the best protection against small-pox known to the profession, and you can assure him, with a good deal of confidence, that his protection is well-nigh complete.

This, we conceive, is what ought to be taught by the profession to the people, and what boards of health and all those in authority in such matters everywhere ought to understand, and be prepared to issue orders accordingly, and see them executed. When this is

done thoroughly, and done everywhere, we will be far on the road to stamp out from among the ills that human flesh is heir to this loathsome and dangerous disease commonly called small-pox. Truly,

W. E. GILLILAND, M. D.

COATSBURGH, ILL., March 11, 1881.

MENIAL AND HUMILIATING DUTIES.

MR. EDITOR.—A passage in the *Advertiser* of March 15th furnishes food for reflection. In an editorial on Foreign Affairs, it is reported that at a recent festival at Berlin one prince handed the soup to the Emperor, while another handed him the wine, and the train of the Empress Augusta was carried by countesses. The whole affair was treated as a political event, and the ancient families did not refuse to perform "menial and humiliating duties." This is, no doubt, very sad to the believers in the natural dignity of man, but what would such a one say to a rumor which prevails, namely, that at the Faculty meetings of the medical department of the oldest university in America the youngest members are called upon when supper-time comes to perform similar "menial and humiliating duties"? If this be true, is the custom calculated to increase self-respect or respect for their elders among the younger members, or the reverse? JUVENUS.

DIABETES MELLITUS.

MR. EDITOR.—Having been a sufferer for many years from the above-named disease, I send a short account of some features of my case, hoping it may interest your readers. I am now sixty-five years of age. Some five years ago I noticed I was passing more water than usual; but, as I was apparently in perfect health, and knew old men were quite apt to be troubled about retaining their water, I did not think of its being diabetes, and paid no attention to it. Two years ago last autumn I had been driven pretty hard night and day, besides being worried in financial matters. I found myself growing weak and passing water every hour in the twenty-four, and I was compelled to lie by. I had a year before tested my urine, and found it to contain sugar; but as I was well and hearty I paid no attention to it, and here was my error. I think, possibly, if I had commenced four years ago to use proper remedies I could have made a recovery partial, if not complete; and here I would advise any one who suspects that he has the disease to have his urine tested, and if sugar is found, to at once commence treatment; for then is the time, if ever, that a cure may be hoped for. At the time I speak of I found the specific gravity of my urine 1035, and I boiled down a pint and one half, and made two and one half ounces of solid sugar; of course, the natural salts of the urine were with it, but that would be a very small part of the two and one half ounces. I gave up practice, except what came to my office and an occasional visit. I put myself at once on a meat diet almost exclusively, and I took of laudanum one drachm, tincture of nux vomica fifteen drops, and the compound tincture of cinchona, enough to make one ounce. This I took daily, and soon there was a decided improvement; the secretion was less, and the

specific gravity came down to 1020. I kept along for some three months, when all at once my stomach rebelled against meat; I was obliged to go back to a bread and vegetable diet, and I could not retain enough of that to support life and the constant waste of the disease; and ever since I have eaten such things as my stomach craved, avoiding, however, such articles as were especially of a sugar-producing nature. After giving up my meat diet the specific gravity became 1028 to 1030. I have boiled it down to solid sugar many times, and found an ounce to the pint (never less) of solid residue. At the time I was the best, and the specific gravity 1020, I did not boil any down, but the tests showed that it still contained sugar. I have used various kinds of mineral waters without benefit, except that the "Commonwealth" spring seemed to help me for a time. I used it for three months, and it failed to help further. I have used for more than a year one grain of S. morphia in an ounce of tincture of cinchona and from fifteen to twenty drops of tincture of nux vomica, sometimes I have added fluid extract of gentian. I have read that there was a wonderful tolerance of opium in this complaint, and it has so proved in my case; I had never made use of the drug before this sickness, and when I was using the laudanum, by way of experiment I took two drachms at a dose and felt no narcotic effect, or very little; it relieved me, and I was free from pain,—of course the morphia has a similar effect. I cannot sleep under the influence of opium, so what I take is at one dose and as early as nine o'clock in the forenoon. I have found anything that worries the mind will at once make my disease worse, and I am satisfied that those who have this strange disease should avoid anything like severe fatigue of body, and it is even more important that the mind should be quiet and free from undue anxiety. I attribute my present health to the care I have taken of myself in this respect; we are so nervous in this complaint that things often magnify themselves, and it is hard to maintain an equilibrium and be cheerful, but it is certainly worth a great effort. My advice to diabetics is to take the best care they can of themselves, avoid all excitement, or anything that calls for extra exertion either of body or mind. I have very little faith in medication; the opium treatment has seemed to do best for me. I have known several cases of the disease, and nearly all have seemed to go off by overdoing and starting up the disease in its acute form, dying in thirty or forty hours, when they, previous to the extra exertion, were able to attend to almost any light business.

R. K. CLARK, M. D.

GEORGIA, VT., March 7, 1881.

PRELIMINARY KNOWLEDGE OF THE CLAS- SICS.

MR. HOLDEN, at the close of a brilliant oration, recently delivered before the Hunterian Society, in accordance with its provisions for a biennial oration in honor of John Hunter, expressed his opinion in regard to the value of a preliminary classical training for a medical student; and as the matter has been fully as much discussed upon this side of the water as in England we reproduce Mr. Holden's words. The opinion of a teacher of forty years' experience must be of interest even to those who differ from him:—

I propose, sir, with your permission, to devote the

few remaining moments to a question which has of late divided society into two opposite camps, — whether we ought or ought not to require from our students a preliminary knowledge of the classics. Greek and Latin literature, whether the R. C. S., or even the universities, insist on its study or not, will ever be held in the highest estimation. The more completely it should happen to be set aside for a time, the greater would be the force of the inevitable reaction which would bring it again into power. The question about which there is a difference of opinion is plainly this: Is it, or is it not, a waste of time for students to spend so many years of their life in the study of Greek and Latin, preparatory to entering the profession? It is a matter of the utmost importance to us personally, and I should be sorry to lose this great opportunity of expressing my own convictions on the subject.

First, therefore, I will ask you, sir, and all who have taken part of late years in our examinations, whether you have found, as a matter of fact, that ignorance of the classics is compensated for by a knowledge of science, and that the best scholars are the worst anatomists. And this, I take it, would be the case if the question were merely one of economy of time; if the hours which are now said to be wasted in learning classics were really better spent upon other subjects. But, since it is a matter of experience that those who

come before us best prepared in professional subjects are just those who have had the most complete classical training, it is evident that any surrender of this training is designed as an indulgence to the less intelligent and industrious who seek admission within our ranks.

The mind must undergo a long training before it is fit to grapple with science, and if we set aside classical education we shall be ignoring the value of the best system of training which exists. In students who have had a public-school training I have found a fuller development of the logical faculty, — a more cultivated memory, a greater grasp and power of combination. I have found the task of teaching them so much easier that I have no hesitation in saying that I can teach such pupils more in two months than others, who have had no like education, in six.

Bearing this in mind, let us strive to raise rather than lower the standard, by requiring a proof of sound classical training from those who, if they have not had this, have probably had little or no mental training whatever. Above all, let us not further hamper our noble profession, which in nine cases out of ten is taken up as a means of gaining a livelihood, with the stigma of being illiterate, nor subject the youths who are to be the future representatives of English surgery to the danger of being looked upon as "symbols" of an inferior education.

Deaths reported 2978; 1095 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas, and fevers) 571, lung diseases 452, consumption 436, diphtheria and croup 191, scarlet fever 98, small-pox 64, cerebro spinal meningitis 46, typhoid fever 35, diarrheal diseases 35, malarial fevers 32, measles 29, erysipelas 18, whooping-cough 15, puerperal fever six, typhus fever two. From *cerebro-spinal meningitis*, New York 14, St. Louis nine, Chicago six, Baltimore and Fall River three, Philadelphia, Milwaukee, and Worcester two, Boston, Pittsburgh, Taunton, Haverhill and Quincy one. From *typhoid fever*, Philadelphia six, Chicago, Lowell, and Lawrence four, New York and Pittsburgh three, Cincinnati two, Brooklyn, Boston, St. Louis, Baltimore, New Orleans, Milwaukee, Providence, New Haven, and New Bedford one. From *diarrheal diseases*, New York 10, St. Louis and Baltimore five, Philadelphia four, Brooklyn three, Chicago two, Boston, Cincinnati, New Orleans, District of Columbia, Lynn, and Somerville one. From *malarial fevers*, New York 14, Brooklyn and St. Louis five, Chicago three, Baltimore and New Orleans two, District of Columbia one. From *measles*, New York 11, Boston eight, Brooklyn two, Chicago, St. Louis, Cincinnati, Milwaukee, Charleston, Nashville, Chelsea, and Pittsfield one. From *erysipelas*, New York four, Philadelphia three, Brooklyn and Chicago two, Baltimore, Pittsburgh, New Haven, Nashville, Springfield, Somerville, and Haverhill one. From *whooping-cough*, Philadelphia three, New York, Baltimore, and Pittsburgh two, Chicago, Cincinnati, Lowell, New Bedford, Milford, and Westfield one. From *puerperal fever*, St. Louis two, Philadelphia, Nashville, Newburyport, and North Adams one. From *typhus fever*, Philadelphia two.

Twelve cases of small-pox were reported in Brooklyn, 29 in Chicago, three in Pittsburgh; varioloid, three in North Ad-

ams; diphtheria 40, scarlet fever 17, in Boston; scarlet fever 23, diphtheria five, in Milwaukee.

In 44 cities and towns of Massachusetts, with a population of 1,124,888 (population of the State 1,783,086), the total death-rate for the week was 20.44, against 21.99 and 22.79 for the previous two weeks.

For the week ending February 19th, in 149 German cities and towns, with an estimated population of 7,760,748, the death-rate was 25.4. Deaths reported 3791; 1656 under five; pulmonary consumption 611, acute diseases of the respiratory organs 352, croup and diphtheria 132, scarlet fever 81, whooping-cough 51, typhoid fever 40, measles and röteln 27, puerperal fever 22, small-pox (Königsberg two, Lübeck, Breslau, Munich two, Aachen) seven, typhus fever (Posen) one. The death-rates ranged from 14.3 in Lübeck to 37.5 in Munich; Königsberg 25.8; Breslau 24.2; Dresden 21.5; Berlin 24.2; Leipzig 23.4; Hamburg 21; Hanover 22.5; Bremen 26.9; Cologne 34.2; Frankfurt 23.2.

For the week ending February 26th, in the 20 English cities, with an estimated population of 7,616,417, the death-rate was 21.9. Deaths reported 3195; acute diseases of the respiratory organs 367, whooping-cough 76, scarlet fever 56, small-pox (London 44) 45, diarrhoea 41, measles 34, fever 25, diphtheria 13. The death-rates ranged from 16.7 in Sheffield to 28.6 in Liverpool; Bristol 18.5; Birmingham 19.4; London 21.5; Leeds 23.7; Manchester 25.9; Liverpool 28.6. In Edinburgh 21.2; Glasgow 23.3; Dublin 38.3.

In the 20 chief towns in Switzerland, for the week ending February 26th, estimated population 522,856, there were 31 deaths from acute diseases of the respiratory organs, diphtheria and croup 15, diarrheal diseases 15, measles eight, typhoid fever six, small-pox four, whooping-cough one, puerperal fever one.

The meteorological record for the week in Boston was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM MARCH 12, 1881, TO MARCH 18, 1881.

WHITE, C. B., major and surgeon. Granted leave of absence for three months on surgeon's certificate of disability. S. O. 57, A. G. O., March 11, 1881.

GARDNER, J. DE B. W., captain and assistant surgeon. The leave of absence granted him in S. O. 16, February 8, 1881, Department of Arizona, is extended five months, and so much of S. O. 34, C. S., A. G. O., as relates to him is revoked. At the expiration of his present leave of absence to report by letter to the surgeon-general. S. O. 59, A. G. O., March 14, 1881.

TAYLOR, B. D., captain and assistant surgeon. Now in San Antonio, will report to the commanding officer, Fort Ringgold, Texas, for duty as post surgeon. S. O. 40, Department of Texas, March 7, 1881.

GIBSON, R. J., first lieutenant and assistant surgeon. Granted leave of absence for one month, and permission to apply for fourteen days' extension. S. O. 47, Department of the Missouri, March 10, 1881.

SUFFOLK DISTRICT MEDICAL SOCIETY. — A regular meeting will be held at the Hall, 19 Boylston Place, on Saturday evening, March 24th, at seven and a half o'clock. The follow-

ing papers will be presented: Dr. C. F. Folsom, Some Points in the Early Diagnosis and Treatment of the General Paralysis of the Insane. Dr. J. H. Whittemore will open the discussion. Dr. F. H. Davenport, A Case of Urethritism. Dr. T. B. Curtis will open the discussion. Dr. H. F. Damon, Clinical Notes on a Case of Glanders in a Woman. Supper at nine o'clock. All members of the Massachusetts Medical Society are invited to be present, and join in the discussion.

H. C. HAYEN, M. D., Secretary.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting of the society will be held on the first Thursday of April, at 10 30 A. M., at the Medical Library Rooms, 19 Boylston Place. M. L. Brown, M. D., will read a paper upon The Gynæcic and Obstetric Uses of Chloral Hydrate. Profession invited. HENRY M. FIELD, M. D., Secretary.

CORRECTION. — The cases of lead poisoning in Dr. Minot's paper, printed in the number for March 10th (page 221), were reported by Mr. T. F. Sherman, and not, as erroneously stated, by Mr. F. M. Sherman.

CORRECTION. — In London letter of February 10th, for Dr. Dyer of Spitzberg, read Dr. Dyer of Pittsburg.

Lectures.

THE NEED OF A RADICAL CHANGE IN THE EDUCATION AND TRAINING OF THE AMERICAN GIRL, AND THE PHYSICIAN'S DUTY THEREIN.¹

BY HAMILTON OSGOOD, M. D.

I WILL ask you to bear in mind that I am endeavoring to prove the need of a change in the training and education of the American girl. But I cannot give the minutiae of a new departure. You will have observed that, in the main, my paper is a criticism. It attempts to show the wrong in order to suggest the right way. Consequently, when I approach the education of the girl, it is with no intention of presenting, *de novo*, an arbitrary system. It is rather with the purpose of showing what a girl's education should not include. I have already mentioned some of the errors of the moral training of girls, but you would not expect me to give details of what a moral education should be. In fundamental points we should be in accord, but in detail we should differ. There is a witty illustration of my meaning: "Iron," says the Professor at the Breakfast Table, "is essentially the same everywhere and always, but the sulphate of iron is never the same as the carbonate of iron. Truth is invariable, but the Smithate of truth must always differ from the Brownate of truth." In respect, then, to the moral basis of the girl's education I will, while reserving the privilege of criticism, merely express the hope that it will be true, simple, and sensible. Her intellectual education I likewise approach with diffidence, for, in the words of Herbert Spencer: "To educate rightly is no simple and easy thing, but a complex and extremely difficult thing; the hardest task which devolves upon adult life." And though I am speaking of the purely intellectual education, I do not for a moment mean to have you think I would separate the mental from the moral, or either of these from the physical training. Yet their isolation from each other, and the failure to realize the absolute necessity of their mutual coöperation, are very common, and do much harm. If we would avoid abnormal and unsymmetrical evolution, these forces must develop simultaneously, move together, go hand in hand. And the criticism of the physician would be necessary only when one of this triumvirate were found to be growing at the expense of the other two. "The growth of the plant," says Johannot in his work on teaching, "proceeds systematically, symmetrically, and harmoniously. Stem, bud, leaf, flower, and fruit, come precisely in the succession necessary to accomplish the highest object of the plant. . . . An excessive forcing of stem or leaf will result in a limitation of flower and fruit. These organs, therefore, develop in due proportion without interference with each other, and, as a natural consequence, avoid loss or waste of force." Applying this illustration to education he says: "The object of education, then, is to promote the normal growth of a human being, developing all his powers systematically and symmetrically, so as to give the greatest possible capability in thought and action. These powers must be trained to act harmoniously, so that there need be no waste of effort in any direction." "The question of compulsory education," says Huxley, "is settled, so far as Nature is

concerned. Her bill on that question was framed and passed long ago. But like all compulsory legislation, that of Nature is harsh and wasteful in its operation. Ignorance is visited as sharply as willful disobedience; incapacity meets the same punishment as crime. Nature's discipline is not even a word and a blow, and the blow first, but the blow without the word. It is left to you to find out why your ears are boxed. . . . The object of what we commonly call education — that education in which man intervenes — is to make good these defects in Nature's methods; to prepare the child to receive Nature's education neither incapably, nor ignorantly, nor with willful disobedience, and to understand the preliminary symptoms of her displeasure without waiting for the box on the ear."

But, in giving her mind its appropriate knowledge, we should not forget the period of life through which the girl is passing. Perceptive studies, or those which appeal to the senses, for childhood; studies which awaken the reasoning powers for a more advanced age, prepare the mind for the reflective studies of middle life. But without the preliminary treatment which develops the imagination and the reasoning powers, the judgments formed by the mind at middle age are apt to be faulty and unreliable, because there is an insullient supply of the materials of thought.

This, according to the profoundest students of the best means of mental development, is the method which should be followed from childhood, in order to give the proper mental direction to later years.

Passing now to the age of twelve years, we find the girl going regularly to school, and forming acquaintance with schoolmates. But the mother should know where she is, and with whom, at all hours. And if she have won the girl's confidence, she can easily avert the injurious influence so harmful at this age. This is of absolute importance, for it is now that the girl's character, thoughts, and feelings, are rapidly crystallizing into the form which is to endure.

"The clay is moist and soft, now, now make haste
And form the vessel, for the wheel turns fast."

In another direction, too, this is a critical age. It is now that the peculiar organization of the girl is beginning to assert itself. It is not enough to wait until nature has made her aware of her sex. What she has gained in physical vigor may all be lost, if in her work or play she be allowed to become unduly fatigued. The trainer never allow a young and spirited horse to be overdriven and carelessly exposed. He knows what the effect of such treatment would be when the animal was called upon to show his best power. And it requires but little thought to see that over fatigue in any direction, during the years which immediately precede the announcement of sex, will detract from the girl's power to meet and bear the change. She shall rather be so trained that she will store up strength upon which she can hereafter draw in safety. It is at this early age, then, that I would have the mother begin those lessons in physiology which, apart from such general instruction in this subject as the girl may receive in school, will have an especial bearing upon her sex. The cruel prejudice against making a girl perfectly familiar with the changes she is approaching is as wicked as it is thoughtless. Every day of our practice brings to our observation ills whose origin lies in this mistaken reticence. It not only injures our girls but the generations which follow them. This undoubtedly stands, *facile princeps*, the great error in the

¹ Extract from an address delivered before the Alumni Association of Jefferson Medical College, March 11, 1881. From advance sheets of the College and Clinical Record.

training of the American girl. She is allowed to approach her physical future blindfolded. One day she is a child. The next, all unprepared, in touching ignorance of the meaning of it all, she enters that world which we call womanhood. Shame upon American mothers, double shame upon American physicians, that this is permitted. This, my brother physicians, is the head and front of my essay. This includes all the rest. For, amazing as it may seem, in nearly all the works on education to which mothers have access, this subject is almost absolutely untouched. And who among us, whose solemn duty it is not merely to heal, but to prevent disease, how many of us see to it that the girls of the families which look to us for advice are properly prepared for this important change in their lives? Do you say this should be the mother's care: such instruction it is her duty to impart? So be it. So say I. But what are the traditions of that mother's training? Was it not also *her* lot to find her way along the life path without that guiding influence which her mother should have bestowed? Was *she* shielded and protected, by gentle thoughtfulness, from the dangers of ignorance at the critical age of her life? This lamentable hiatus in the training of American girls is not of to-day's creation, and generations may pass before the error is blotted out. For, the needed change in this direction must begin in the training of girls now growing into womanhood: and let it be with the hope that they, in their turn, will prepare their daughters for womanhood.

Last summer a case of chorea in a girl nearly thirteen years of age showed me the double necessity of preparing her mind for the physical change which was very near. The cultured mother objected, because the child was "so innocent," not realizing that this innocence was merely *ignorance*. I overcame her prejudice, which I found was due to the fact that she in her childhood was neglected, as she was neglecting her child. This is a typical but a sadly common case. In view of their undeniable need of physiological intelligence, it seems incredible that girls are thus purposely kept in ignorance of their own structure, and are permitted to grow up utterly unprepared for the varying stages of their development. But I believe we should find that three fourths of our female patients were not only ignorant of their physiology at this critical age, but, though cultured it may be in other respects, are still ignorant, even though they may be mothers.

Take the average girl of to-day, at the age of nineteen, we will say. This girl, who would blush if obliged to confess ignorance of Buddha, or Apelles, or some fourth-class character of mythology, will calmly admit that she not only knows nothing of the physiology of her functions, but that she is perfectly indifferent to such knowledge. This is a monstrous error; one into which our girl shall by no means be allowed to fall. She shall be so trained, between her twelfth and fourteenth years, as not only to be mentally but physically prepared for the metamorphosis which is coming to her. She is old enough to know how to live physiologically, and shall gradually be taught the great and divine meanings of womanhood. She shall be impressed with a feeling of reverence for her highest mission in life, in spite of as many women's rights doctrines as might fill the shelves of a Bodleian library. The women of to-day who are striving to put off and fly from the true mission of true women, remind one

of the boy, who, in order to rid himself of an aching tooth, filled it with gunpowder, put a slow match to it; and then ran. The girl shall be taught that "if the boy is father of the man," the girl is mother of the man. From the age of twelve to the day of her marriage she shall be made to feel her responsibility toward her future, and those whose lives will, one day, be in her keeping.

I do not forget the admirable exceptions among our women; those who have dignified callings entirely disconnected from, and which exclude the duties of home and motherhood. All honor to them. They are free to follow their chosen path. But the typical woman, no matter how rare her culture, will not fail to confess that the deepest wish of her heart is to become the centre of a home, as wife and mother. It is her nature and her mission. Where can she find a higher? She may wish to follow another way of life. She may be forced to do so. But I agree with a recent writer, who says: "A woman has a right to do everything she can do, provided she does nothing which will unfit her for bearing and rearing healthy children. It is pitiful to think there are multitudes who have no choice between employments, which unfit them for motherhood, and want. It is pitiful that there are mothers who live their whole married lives in conditions which utterly unfit them for the functions of maternity." The best rules of development for women who are to marry will result equally to the best good of women who are not to marry. If the laws are essential to one they are to all. Let it be understood, however, that the duties of home do not deprive a woman of interest in matters outside the family. There is no better influence in social questions than that of an intelligent mother. Until her family is reared, however, the home and her children are her first and highest duty. "No woman," says Sidney Smith, "should forsake an infant for a quadratic equation." Upon the good health, the self-care, the wise living of mothers, depends the future of our country. For, otherwise, how is our country to be provided with stalwart men and noble, vigorous women?

It is only too true that in the past and present of many nations, woman has been so misunderstood and unappreciated that a revolt has caused many to swing to the other extreme. The true mission of women is not to be "merely a cradle and a grave," as Miss Brackett too bitterly says, but that nobler being in whom lies the hope of our race.

"One of Nature's ends, or, rather, her supreme end," says Spencer, "is the welfare of posterity." "The first requisite to success in life," says another, "is to become a good animal." Paraphrasing Herbert Spencer, I would say that to have a nation of good mothers is the first requisite of national prosperity. This is what should be impressed upon the American girl, and she should be taught that her share in this desirable result is to be attained only through conscientious care of her body and its functions. She cannot escape from herself. She cannot change her sex. The restlessness which is so common among our cultivated women is a mistaken and fruitless insubordination; an endeavor to escape the duties which are the glory, and should constitute the chief joy, of woman. Rebellion against them is a criticism upon her Creator.

The mother is the proper physiological teacher of the girl. But she can hardly accomplish this duty without help from the physician. In and through all

this development of the girl's knowledge of herself, his influence should and must almost necessarily be felt. His duty it is to see that the mother clearly recognizes and understands hers.

The girl *will* know what is hidden behind the deplorable mystery which surrounds these subjects, and if she be not told by her mother, she will obtain her knowledge in garbled, imperfect, and indelicate form, out of the home; and her modesty will thus be hurt, and her natural purity be tarnished. But if there be perfect openness between herself and her mother, if she be instructed in a frank and practical manner, the mystery disappears, the purity remains, and the imagination of ignorance will be put at rest. Unbroken confidence between mother and daughter will, moreover, be to the latter a wall of defence against injurious influence. How mistaken mothers are in failing to establish this fearless trustfulness on the part of their daughters!

Our girl is now being fully prepared for the coming change in her physical being, and shielded and protected by the watchfulness of the mother. After she has crossed the threshold of her womanhood she shall be so guided that neither study, exercise, nor amusement can interfere with the onward sweep and development of her physique. Like King Lemuel's ideal woman "she strengtheneth her arms, she girdeth her loins with strength." She shall be shown that, although she may have the studies of the boy, she cannot pursue them with the same unbroken regularity. If this be a disappointment, let her be taught that underlying all the intellectual ambition of the growing girl should be submission to that higher law of sacrifice which every woman must recognize and accept if she would reach her best possibilities. This apparent loss becomes rich gain to her in the freshness of spirit and depth of receptivity with which she renews her work. And if she ask: "Am I to be irregular in study, am I to deny myself legitimate pleasure?" The reply should be: "Yes, if in that way you can attain a higher development."

One especial danger to which the girl might otherwise be exposed, namely, that of cultivating an unhealthy imagination, should be avoided by excluding all pernicious reading, in the shape of the fashionable novel, all conversation which her mother may not share, and moods and idleness which would lead to morbid introspection. In other words, by the use of a variety of means, her thought shall be kept bright, pure, and healthful.

An error of the day is that a girl is expected to complete her education by her eighteenth year. An age at which lads are but little more than half way in theirs. Everything in the shape of culture is crowded into the years during which the girl should be cultivating the physical strength, common sense, and practicality which are to be of life-long benefit to her and her descendants, while half the so-called culture with which fashionable education crams the girl is of little use and is quickly forgotten.

The women who constantly assert that the girl can study incessantly and without physical harm are simply mistaken. "Physical degeneration in girls," says Spencer, "is a result of excessive study. High pressure in education is worse for girls, because they are debarred from the vigorous recreation of boys, and thus the evil is intensified." Less study and more exercise should be their rule. But the two may be so arranged

that the girl will have a truer culture and a better development than if she be allowed to rush, at constantly increasing speed, through her curriculum of education. While confessing that women can work better when their occupation is frequently intermitted, Mary Putnam Jacobi thinks she has proved that only forty-six per cent. of women need periodical rest. I should be glad to question the remaining fifty-four per cent., and do not doubt that the minority would become the majority if duty were obeyed. I would make the rule absolute, that our girl's education should go hand in hand with, and not exceed, her physical growth. If this rule be disobeyed, as is the custom, especially among young women who are ambitious students, the education will be of little value, the physique, perhaps, of none at all. In his monograph on insanity, Dr. T. W. Fisher says "Continued study severely affects the health of young girls. They risk their lives at the *susceptible* period and break down afterward." Upon good health and upon the ability to perform her functions easily and naturally, depends, in a very large degree, the comfort and happiness of women in later years. Our girls rush through the years of their adolescence utterly regardless of the great need of intervals of rest. And if the careful mother or the watchful physician insist upon periodical repose, they submit to it most ungraciously and with an impatient criticism upon their sex which is pitiful. They try to live as if there *were* no swing of tide in their organism. They try to live down and put under reckless foot the necessities of their sex. But it is the old fight with windmills, with this difference: Don Quixote recovered from his hurts, but they in too many cases never do. And yet, when the day comes, they do not hesitate to assume the office of maternity, and thus, as a result of their foolishness and the indifference of their mothers, they bequeath misery unto the third and fourth generation. Influential women write that girls do not need periodical rest. That if, forsooth, they but observe the laws of health they can go straight on, like men. Query: What are the laws of health? The trouble is that laws which are essential to their well-being women consider arbitrary.

A fair reply to these mistaken advisers is the court scene between Choate and Webster. Choate's client claimed that the patent car-wheel of the defendant was an infringement upon his, and Choate, with brilliant eloquence, occupied three days in proving that the new wheel in no way whatever was an improvement upon the original wheel. When Webster rose to reply the court was crowded in expectation of a superb exhibition of forensic power. With one magnetic glance Mr. Webster took in the entire jury, then tilting upon the table the models of the two wheels, he said: "Gentlemen of the jury, here are the two wheels. Look at 'em." He won his case. In this way I would have a medical jury decide the case before us. I would bring before them a girl who has been properly reared and a girl of the high-pressure system, and say: Look at them!

I can mention two women, honored by our sex as well as their own, who are largely responsible for the present restlessness of many of their sisters. They are noble, cultured women, of great influence. One of them confessed to a patient of mine, that last year nervous exhaustion nearly made her insane, and incidentally remarked that at her last confinement she sent off her proof-sheets, and at the same moment called for doctor

and nurse. You would be surprised if I told you her name. The other admitted that in spite of all she had said in public touching the rights of women, her persistent, unrestful labor had so exhausted her that she had modified her views, but would not confess it to any man living, and would not have the public know of it for the world. I could quote other equally significant confessions. These cases are only a fresh suggestion of the battle with the windmills. It would seem as if these women ought to know the exact sense and weight of what they affirm and teach. But do they realize the actual condition of our young girls, and is this condition entirely due to mistakes in dress and party going? Do we physicians not know there is another side?

THE ELECTRO-MAGNET IN OPHTHALMOLOGY, WITH THE DESCRIPTION OF A NEW MAGNET.

BY HENRY W. BRADFORD, M. D.,

Assistant Massachusetts Charitable Eye and Ear Infirmary.

THE rapidly extending use of the electro-magnet for the purpose of removing fragments of iron and steel from the interior of the eye, the slight attention previously bestowed on this method of procedure, and the imperfect knowledge of the subject displayed in many of the published articles, have induced me to bring forward the following views. They are the result of several years' practical study. And their main object is to demonstrate that in the application of a properly constructed magnet we possess an efficient means of treating cases for which enucleation has hitherto been practically considered the sole resort.

Magnetism may be applied to the eye from either a permanent or an intermittent source, that is, either from a so-called permanent magnet, which, once excited, retains its magnetic power indefinitely, or from a magnet which becomes such only when excited by the electric current. And the superiority of the latter is incontestable. It exceeds its rival by many times in power, when of less weight and smaller size. The permanent magnet is, moreover, open to the objection of being liable to a constant dissipation of its energy upon receiving any sudden shock or blow, upon moving across the magnetic meridian of the earth, and even when at rest, unless guarded by an armature whose weight nearly equals its suspensive power.

The electro-magnet must then be the one employed for the purposes of ophthalmic surgery. And in modeling such an instrument for use about the eye, it is evident that we must combine the minimum of size with the maximum of power. To this may be added, for the sake of convenience, with the smallest and most compact battery that proves itself available.

It is in precisely these three requisites that previous electro-magnets have been deficient. When small their power has been insufficient. When large they have been clumsy, have supplied little power in proportion to their size, and have required a large number of cells to develop their full force.

Having, in the course of the experimental study of his subject, constructed some fifty magnets, of every variety of shape and size, I would advance the following magnet, as giving the best results accomplished:—

The core is composed of soft Norway iron, one third of an inch in diameter, and two and one half inches in length; to one end of this solid cylinder is riveted a flat circular disc of the same material, one inch in diameter, and one sixteenth inch thick.

The surrounding helix is composed of insulated copper wires, weighing twenty-nine grains to the foot, making eight convolutions of one and three quarters inch in length.

The polar extensions are respectively five, four, and three thirty-seconds of an inch in diameter, and one half inch in length; their suspensive power equals twenty, sixteen, and eleven ounces each; when an armature of soft iron, one inch by one tenth in diameter is used, which is within two ounces of the saturation point.

The battery used is a single bichromate of potash cell, having eight square inches of negative surface. The magnet weighs about five ounces, and the intensity of its field by the addition of another cell is made as great as that of a magnet capable of lifting a ton.

The use of large magnets capable of lifting enormous weights offers no advantage over the one above described, as their field is no more intense, and, unless the foreign body is of many pounds weight, does not exert any greater force. It may be laid down as a law that the *size* of the magnet should be in proportion to the size of the body acted upon; if a large body of iron is to be suspended, then a large battery power and correspondingly large magnet must be used, but should the foreign body be of small size such as would be met with in the eye, a small single cell magnet magnetized to saturation will give the same amount of suspensive force, as the magnetic field of each will be the same in intensity, differing only in size.

In regard to the quality of material nothing but the most soft and pure iron should be used; the use of impure commercial iron is open to the objection that its saturation point is much lower than that of the brand known as Norway iron, and as it retains its magnetism, upon making attachment to the battery a second time this may have to be overcome, thereby raising the temperature and lowering the magnetism; this takes place, if the poles of the magnet are reversed, by connecting the battery in a different manner than at the first.

Having finished the construction of the electro-magnet we will pass over to its application and use in ophthalmology.

Foreign bodies that enter the eye may lodge in any one of the following structures, and, commencing with the most superficial, the cornea, they might pass through the anterior chamber, the iris, lens, vitreous, and choroid. Of the metallic substances which enter the eye none are removable with the magnet except pieces of iron and steel. Those that enter and lodge in the cornea may be divided into two classes, first

those minute fragments which enter its surface and are removed by means of the needle, and over which a magnet has no practical effect because of their small size, and, second, those which have an appreciable size. These latter may be extracted in the following manner: The point of the above-constructed magnet is brought in direct contact with the foreign body, and then moved away to the distance of a fourth of an inch; this manœuvre is repeated several times, and if the case is seen before the corneal wound has had a chance to heal, the foreign body will finally be found adhering to the point of the instrument. If, however, the wound has healed a change in the procedure is necessary. While keeping the magnet in close proximity to the foreign body, an incision through the wound is to be made for the purpose of allowing a free exit, the manœuvre of touching and withdrawing the instrument must be gone through with again and again, and ultimately the foreign body will be easily removed. These two methods are entirely sufficient for the extraction of all fragments in this tissue, as long as any part of them is in the cornea, even though the greater portion of their bulk projects into the anterior chamber.

The anterior chamber may be the resting place of a fragment, and if so, it should be drawn to the margin of the cornea, and extracted through an incision in that region either by the forceps or magnet, at the option of the operator, who should bear in mind the importance of keeping the magnet in close proximity to the metal to be extracted if forceps are used, in order that the fragments may not be lost by means of the forceps slipping.

Fragments situated in the iris may be extracted by two different methods by the use of the attractive or suspensive force; in the first method the magnet does not enter the eye at all, but exerts its influence from the outside in the following manner: The eye is seized with a pair of fixation forceps, an assistant keeps the point of the magnet directly over the fragment imbedded in the iris, the operator, with a stop needle, enters at the margin of the cornea nearest the fragment, in a horizontal plane, and with the extremity of the needle loosens the fragment from its point of attachment, the magnet then seizes and withdraws it to the edge of the cornea, where an incision is made for its removal. The second method, which is by far the simplest, is to make an incision nearly at the edge of the cornea, and pass the point of the magnet directly inwards until contact is made, and upon withdrawal the fragment will be found attached to the polar extension; the certainty of this fact is assured, as this magnet is able to draw through normal iris tissue a fragment of iron the size of a pin head.

Fragments imbedded in the lens may, if a traumatic cataract has formed, be removed by either of the above stated methods. If, however, a foreign body is found resting against the anterior capsule and external to it, the magnet alone must of course be used to effect its removal, an incision through the margin of the cornea being practiced for that purpose.

Fragments in the vitreous may be classified under two heads: those that are fixed in position, and those that are free; in the former case no attempt at removal by means of the attractive force of the magnet will be successful, except by bringing the point of the instrument in the closest proximity to the foreign body when we no longer use this power, but its associate,

the suspensive force. In other words, contact with the body should be made with the magnet in order to overcome any adhesions that may exist. This, however, does not apply when the fragment exists in the vitreous, unattached to any surrounding tissue, for then the attractive force of the magnet will draw the body to the choroid at the nearest point, from which position it can be removed through an incision; this action, however, is not an instantaneous one, for the time needed in the manœuvre will vary according to the consistency of the vitreous and size of the foreign body; should the fragment be fixed in the substance of the choroid and sclera the eye should be rotated in the necessary direction until the site of impactment is brought into view, and in order to accomplish this some division of muscle may be necessary in order that sufficient rotation may be accomplished. An incision is then made as close as possible to the imbedded body, and the magnet, which, during this time, is held in position to keep the fragment from being dislocated, should be passed straight into the eye, avoiding all lateral movements; upon withdrawal the fragment should be found adhering.

Having stated the method of treatment for fragments which may lodge in any of the different tissues of the eye, a few remarks in regard to the general facts of the employment and use of the magnet may be introduced. The amount of suspensive power of any magnet, when saturated, as every magnet used in ophthalmic surgery should be, depends upon the size of the foreign body. Hence, the larger the fragment the more probable its removal, and, conversely, the smaller the fragment the more difficult its extraction. Finally, a point may be reached where the resistance to be overcome exceeds the amount of polarity capable of being induced. This is illustrated in the case of minute foreign bodies in the cornea, where the magnet is of no avail. All incisions for removal of foreign bodies anterior to the plane of the lens should be marginal incisions of the cornea, those that concern the vitreous should be scleral, and made posterior to the ciliary border; in both cases, by so doing, the ciliary body is avoided, and in the latter case the surrounding tissues form the best support for the wound.

One important point in regard to all incisions made for the entrance of the magnet, and the removal of a foreign body from the eye, is *that the cut should be not one with parallel edges, but T-shaped*, as in the former case, when the extraction of the foreign body takes place, it is invariably stripped off the end of the magnet, and is retained at the site of the wound, or drops into the interior of the eye. This is a foregone conclusion unless the lips of the wound be held apart, and no amount of skill or carefulness upon the part of the operator can guard against it, unless the incision is of the above-mentioned shape.

Every magnet having a north and south pole, the supposition would be that they would have the same amount of suspensive force: this, however, is not so, and the explanation of this fact must be sought for in the laws of tension of the electrical current. Should we wish to gain the maximum of attractive force the magnet must be constructed with a diameter proportioned to its length as one to twenty-four or more, this of course, requiring more battery power.

The following cases of removal of fragments of iron and steel from the eye have occurred in the clinic at the Massachusetts Eye and Ear Infirmary. This elec-

tro-magnet or modifications of it have been used, and the gradual decrease in size and the increase in suspensive force of the instrument are worthy of notice.

CASE I. November 18, 1879. F. S., machinist, aged twenty-four, received a blow upon the eye while at work chipping steel; piece penetrated cornea, and lodged in the substance of and posterior to the iris, with an exposure of only a point of one of its extremities upon it. The lens was opaque. Iridectomy was attempted, but unsuccessfully, hemorrhage ensuing, the fragment disappeared, and could neither be seen or felt; the point of the electro-magnet was then passed into the eye at the place where the foreign body had been situated, and after the second trial it was seen engaged in the wound and removed with forceps. The magnet used weighed seventeen ounces, and had a suspensive force equal to eight ounces. Dr. F. P. Sprague, in whose clinic the case occurred, soon after removed the cataract, and when last seen, August 16, 1880, the patient had vision of six eighteenths.

Details of the second and third cases occurring in the services of Dr. B. Joy Jeffries, and Dr. C. H. Williams, may be found in the December 30, 1880, number of the Boston Medical and Surgical Journal. The magnet in each of these cases weighed eight ounces, and the ratio of suspensive force had increased to sixteen.

In the fourth case, that of J. S., stone cutter, aged twenty-seven, who came to Dr. Henry L. Shaw, the foreign body, a thin scale of steel, had passed through the cornea, and projected nearly two thirds its diameter into the anterior chamber. As the corneal wound had partially healed over the fragment, all attempts towards its removal were unsuccessful until the wound was reopened with the knife, when the fragment was immediately grasped by the magnet and withdrawn. The weight of the instrument, whose construction was the same as previously described, was five ounces, and its suspensive ratio had increased to over twenty.

The point of the magnet, shown in the engraving, can be removed, and smaller ones attached. Several of these accompany the instrument, which may be obtained of the manufacturer, Thomas Hall, 19 Bromfield Street, Boston.

THE TREATMENT OF STRAINS AND SPRAINS BY COLLODION.¹

BY A. S. BLODGETT, M. D.

PHYSICIANS are called upon to treat a great number of injuries to the joints in which there is no discoverable fracture or dislocation, but which are considered to be partial dislocations of the less mobile articulations, accompanied by more or less extensive rupture or laceration of the ligaments about the articulating surfaces, with some degree of effusion into the cavity of the joint, and often a very considerable amount of hemorrhage and sanguification in the neighboring soft tissues. The nature of the injury makes its recovery a gradual process, the tissues involved are often those in which reparative operations are carried on slowly; the external swelling and the effusion into the articulating cavities are both mechanical hindrances to recovery, so that healing of the lesion can hardly be looked for until they have subsided.

¹ Read before the Suffolk District Medical Society, February 29, 1881.

Added to this is the fact that the most frequent seat of this class of injuries is some joint in the articulations of the ankle or foot, and we have in the location of the accident, perhaps, the most important obstacle to a speedy recovery from the injury. There are but few persons who so completely follow advice as to grant the injured limb freedom from use, for most people will persist in a certain amount of walking with the injured foot under any circumstances. It is often impossible to convince the patient that it is necessary to favor a *strained* joint for the same reason that this is necessary in a dislocated one. Oftentimes the difference between a strain and a dislocation is simply one of degree.

For these reasons the public has learned that recovery from a strain is usually a very slow process, subject to frequent interruptions from the many accidents to which the foot and ankle are exposed in walking, which constantly retard recovery and often are so severe as to prevent any reparative process at all. The formula of the domestic medical adviser that a sprain is often a more prolonged injury and slower to heal than a fracture or a dislocation is, therefore, in most cases correct. The treatment of sprains and strains is often in the highest degree difficult and unsatisfactory; the injury, when located in the foot or ankle, is in a part of the body where the anatomical proportions of the extremity make it unusually difficult to apply many desirable forms of external dressing. The whole limb is rendered useless for purposes of locomotion by any special treatment of the injured portion, and the discomfort and annoyance to the patient are very considerable.

Cold applications or evaporating lotions often macerate the skin and occasion soreness, and the chilling sensation is sometimes so uncomfortable, not to say harmful, to the patient that in some cases this mode of treatment has to be abandoned.

If there be an open wound at the seat of the strain or sprain the treatment of the case is still further complicated. An apparatus for restraining the limb in an immovable position is not often advisable, because of the swelling and other inflammatory conditions of the limb, and it is not desirable to apply an unremovable dressing to any lesion where it is possible to avoid it. It is safe to say that few patients would submit to it if proposed.

It has been my fortune to see quite a number of cases of this injury, and I have treated them according to the methods generally employed in such accidents, and have met with the average amount of success in their recovery; that is to say, after a longer or shorter period of disability the patients have regained the use of the joints, with the usual experience of relapses and weakness for a certain length of time afterward, when the limb is usually fully restored.

In the winter of 1878 I sprained my own ankle, and within the usual time found the parts all about much swollen, the pain considerable, and disability nearly complete. I tried to adjust a bandage, but succeeded only indifferently well, for at the best it would not do what was necessary, and was not easy to retain in place. Treatment by evaporating lotions was so troublesome to me that I soon discontinued all measures of that sort. I was resigning myself to let the sprain take care of itself, when it occurred to me that the application of collodion so prepared that it would contract in drying might be of some service. I made the trial, and was surprised and pleased at the result. For a

few minutes no appreciable effect seemed to follow, but after several coatings there commenced a contraction of the whole layer of collodion from all directions at once, to a much greater degree and in a much more efficient manner than any bandage could possibly effect. The contractile power of the collodion was so great that it seemed as if it would divide the skin at the border of the film. Some of the hairs around the ankle were accidentally included in the collodion film, and were so violently pulled upon that several of them were actually drawn out of the skin. The discomfort attending the contraction of the collodion subsided in a short time, and gave way to a feeling of coolness in the ankle and relief from the pain. The skin became drawn into wrinkles in all possible directions, with a positive and marked diminution in the measurements of the ankle, due to the decrease in the effusion in and about the injured part. After some hours the collodion film cracked in many directions, thus becoming divided into small scales, which I picked off. The skin was not in the least irritated or inflamed by the application. Another fresh coating consisting of several layers of collodion was at once applied before putting the foot to the floor, and the same powerful contraction and a similar diminution of the swelling was effected as at first. In the short space of three days the ankle was restored to its original size, and there was a total absence of pain and tenderness in the joint. I was able to walk without pain, unless the foot was set upon some inequality in the ground, when the strained place of course became painful. In a week I found myself quite well, and have never had a relapse, which I consider the more remarkable as I am not particularly careful, and am upon my feet a great deal.

Soon after this time a pedestrian of some note slipped in a walking match and strained his right ankle. He was ambitious, and considered the accident too trivial to merit attention, and frequently hurt the ankle by standing and walking upon it. In a few weeks his ankle was swollen, tender to the touch, and painful in walking, subject to continual injury from the slightest misstep, and the occasion of much inconvenience to the patient. In this unfavorable state of affairs, treatment by collodion was advised, and the patient left for New York. I have not seen him again, but heard a few weeks afterwards that by the use of collodion he had fully recovered from the weak condition of the ankle, and was less liable to hurt it by a mis-step.

CASE III. A physician in this city made a misstep upon a grating over a hole in the pavement, and fell, spraining the ankle badly and also inflicting a deep punctured wound by some blunt instrument which could not be found afterward. The wound had lacerated edges and a large opening from which a portion of fatty tissue was protruding. The whole foot was greatly swollen, pain was considerable, and the disability complete. With scissors the protruding fragments of fat tissue were cut away, even with the surface of the wound, a square piece of clean, soft linen was laid upon the wound, and over this a larger piece of adhesive gold-beater's skin was applied, thus sealing the wound from the air. Collodion was then applied in several layers over the whole, and continued for a considerable distance upon the uninjured parts of the foot in all directions. When this was dry and firm, cold evaporating lotions were directed, and were faithfully applied. The effect of the cold was fully obtained in the diminution of heat in the swollen foot, but the

most desirable feature was the entire absence of any maceration of the skin or chilling sensation. It was, in fact, a *dry cold*, such as is obtained from an ice-bag, so thoroughly was the foot protected from moisture by the collodion. Not a drop of water reached the wounded spot, and nothing was discharged from it but a little clear serum at the time of the first application, which appeared to be mechanically squeezed out of the flesh from the compression of the tissues by the collodion. The pressure of the parts beneath by the contraction of the collodion film was moderately painful for a few minutes, and then absolute ease was obtained. There was no return of pain. The wound was not disturbed, the dressing was not changed. Healing of the lacerated surface took place by first intention and without suppuration, and, contrary to advice, the patient was walking in four days, without pain, and has remained perfectly well ever since.

CASE IV. An athlete, while turning somersaults, failed to alight where he had intended to, and came to the floor with the right foot resting half on, half off, a thick mat. The result was a severe sprain, which the patient aggravated by endeavoring to "work it off," by standing squarely on the foot, rubbing it, etc. I was called the next morning, and found the foot much swollen, painful, hot, and entirely disabled. After bathing and carefully drying it, collodion was applied over the seat of the sprain, and carried for some distance on to the sound skin around. Vigorous contraction followed, and cold evaporating lotions were applied. In twenty-four hours the swelling had almost entirely subsided, the temperature of the part had sunk to normal, the pain had disappeared, and the relief was so great that the patient felt inclined to put on his shoe. Here, too, the effect of *dry cold* was obtained. Only two visits were made, and in four days the patient was walking in a high-laced shoe, without pain or discomfort. He was advised to continue the collodion for at least two weeks. I do not know if he followed my instructions, but he is perfectly well, and practicing athletic feats every day.

CASE V. A banker on State Street stepped from a horse-car, and strained his foot. He walked a little every day upon the injured foot, and every day he would in some way "tip it over," as he said, until it grew very painful, and threatened to become permanently weak. Under these unfavorable circumstances he was advised to apply collodion, and did so. After five days he reported that the pain and tenderness had entirely subsided; the liability to "tip over" was becoming remarkably less, and the feeling was as if a stout, supporting bandage were accurately adapted to the foot and ankle, which exercised gentle and continuous pressure in any position of the foot. The continued use of the collodion in this gentleman's case, also, has resulted in a perfect cure, when the prospect was that the ankle would remain weak, and become easily strained by any false step.

CASE VI. A young gentleman strained his foot in the gymnasium, the location of the injury being in the articulation between the scaphoid and the cuneiform bones. Before I saw the patient he had already made a vigorous application of tincture of arnica, followed by a similar application of a domestic preparation called "balm of Gilead," which is a tincture made from the buds of the tree which is known by that name. I did not know of this when I examined the ankle, which I found much swollen, very hot, and quite pain-

ful. The superficial tissues were quite oedematous and boggy, and the general appearance was that of a bad injury. It was impossible to examine the state of the joint satisfactorily on account of the pain and swelling, and collodion was applied as in the other cases. The next morning the swelling of the foot was not diminished but was rather increased, and beneath and around the film of collodion was an acute traumatic eczema, the result of the applications which had been made to the ankle the day before, which was also developed on the right hand of the patient, where the lotions had come in contact with the skin while rubbing the foot.

In this case all active treatment of the strain was at once discontinued, and the foot and hand were wrapped in cloths spread with diachylon ointment, which had the effect of gradually reducing the eczematous inflammation, until at the end of three weeks a large shoe could be worn, and in one week more the patient was able to go to his business. The strain was not materially influenced by the treatment of the skin disease, but was necessarily kept at rest, which did it some good. Upon trying to walk, however, at the end of three weeks, it was still weak and painful. Collodion was now applied with the effect of rapidly increasing the strength of the foot, and all pain soon disappeared. The patient has been to his office every day, and has no further discomfort.

CASE VII. Mrs. J. A. made a misstep, and had the usual symptoms of sprain, namely, pain in using the foot, considerable heat, and very great swelling. Collodion was applied, as in the other cases, with the effect of at once reducing the effusion, and in a week the foot was no longer painful in walking, though still somewhat weak. In a fortnight the recovery was complete, and although the patient is a large and heavy woman there has been no relapse.

CASE VIII. F. P., an oarsman of considerable celebrity, slipped while running, and suffered a subluxation in the articulation of the fifth metatarsal bone of the left foot with the tarsus. The injury was accompanied by a noise like the breaking of a stick, which was distinctly audible to the bystanders. When I saw him the foot was painful to the touch, swollen, hot, with all the signs of an extensive injury to the joint, and a partial dislocation of the metatarsal bone, which was more freely movable than its fellow on the other foot. The foot was gently washed, and then parallel lines were drawn upon the skin with ink. Collodion was applied in six layers, and soon a powerful contraction supervened with the effect of diminishing the distance between two sets of lines from 12.5 mm. to 10 mm., or twenty per cent. of its breadth of surface, and from 15 mm. to 12 mm., or twenty per cent. of its breadth respectively. The ratio of contraction is strikingly similar in these two measurements, and I feel quite certain that other experiments will show a permanent coefficient of contraction which will only vary somewhat in amount, according to the location of application and the quality of collodion employed.

The uniform result which followed the use of contractile collodion in these few cases seems to me a sufficient reason for desiring to call the attention of the profession to this method of treating strains and sprains, particularly in and about the ankle. These cases may be supposed to represent the majority of such injuries as they present themselves in daily practice, and I consider them without doubt to be such as would other-

wise have been a source of trouble for weeks, as is usual under ordinary conditions. The treatment by contractile collodion greatly accelerated the recovery, besides restoring to the injured parts an almost perfect immunity from relapse, which is the exception in the healing of strains and sprains.

I do not remember ever to have heard of the use of contractile collodion in the treatment of sprains, and I have never known of its being employed by any person for this purpose previous to the injury which I sustained in my own ankle. This was my first experience in its use, and the result was so satisfactory that I have employed it in all appropriate cases occurring in my practice since that time. In each case its action has caused great surprise to the patient, and the treatment thus far is perfectly satisfactory. I do not know any objection to its use either from its composition or from its retracting power. It seldom causes any irritation of the skin, it does not interfere with the circulation, it never endangers sloughing. The fact seemed to me quite remarkable that, although the contraction was very powerful around the ankle, there was never any puffiness or swelling about the toes or any part beyond the ankle. I do not think a bandage could possibly be applied so as to exercise a similar compression upon the parts beneath without occasioning swelling of the parts beyond the bandage. A very desirable quality in collodion in the treatment of any accompanying wound, as in Case III., is the fact that it forms an impervious covering over the wounded surface, thus hermetically sealing it from the air and from the dangers which often threaten an open wound by infection from this source.

The adaptability of this mode of treatment to cases requiring the application of cooling or evaporating lotions is also of great advantage. The refrigerant is applied directly to the points where such an action is most desirable, and exercises its full force in the way of reducing the temperature of the part, and yet it does not absolutely touch the skin. The result of the protection to the skin is, that the effect of a dry cold is obtained instead of a wet, chilling cold. The skin does not become macerated and soggy from the action of the cold application, and the sensation of the patient is much more comfortable, not to say agreeable, than from the contact of a refrigerating application. Indeed, the film of collodion is so admirable a conductor of heat that I have seen the temperature in a sprained ankle become reduced from this alone, when I am convinced that without the collodion film an evaporating lotion would have been indispensable in the local treatment of the injury. The skin is not thickly covered as by a bandage, but a thin transparent film is spread evenly over its surface, through which every symptom in the injured part can be distinctly and clearly recognized and every shade of color in the skin be plainly discerned. After some hours the film already applied becomes cracked in the lines of its wrinkles when it may be easily peeled off and a new film immediately applied to the same spot, by which all the benefit of a new, fresh compression of the parts is at once obtained.

The treatment may be continued indefinitely. Before applying the collodion it is advisable to gently wash the part to be treated with soap, in order to remove any oily or greasy matter from the skin. These substances might decompose beneath the film and irritate the skin, and they might also prevent the collodion from adhering perfectly in every part. It is

desirable to avoid both these contingencies, and for these reasons I always wash the ankle and dry it carefully by pressing a towel upon it *without rubbing*, by which the moisture can be completely removed, when the collodion may be at once applied. Each additional coat of collodion strengthens the layers already applied, thus acting with a cumulative power in compressing the part and reducing effusion about the seat of injury.

Among the advantages of this mode of treatment are, briefly, prolonged elastic compression in parts notoriously difficult to bandage properly; waterproof protection to the skin from external irritants or applications; hermetical sealing up of wounds in the region of the strain or sprain; constant access to the part without the removal of dressings; an uninterrupted view of every part of the injured limb; reduction of heat in the tissues; great acceleration of the process of healing with perfect restoration of function; a great degree of immunity from relapse; and absolute simplicity in application.

So far as my limited experience warrants an opinion of collodion in the treatment of strains and sprains, I am inclined to consider it by far the best, simplest, and most satisfactory method I have ever known, and I am confident that others will obtain equally pleasurable results in similar cases. I think it more than probable that collodion may prove valuable in the treatment of certain other diseased conditions, upon which I trust to be able to communicate some observations at a future time.

The degree of contraction depends much upon the quality of collodion employed. There is a *flexible* collodion which contains castor oil; this does not contract at all, or but very slightly, and will not do the work. The so-called "*contractile* collodion" must be employed for this purpose. It yields uniform and satisfactory results and is quite durable. It is very volatile and should be kept stoppered, and when being used the finger should be tightly applied to the mouth of the bottle. It is also liable to explode, from the ether it contains, if brought too near a flame, but is fully as safe as ether, and we all use this agent by day or by night without accident.

To obtain the contractile effect of collodion it is necessary to apply several coats successively, one upon the other. I think I have never applied less than six layers, which is easily accomplished as the collodion dries very quickly and a second coat can be applied almost as soon as the first is finished. If for any reason it should become desirable to remove that which has been applied this can readily be done by means of a small quantity of ether, which dissolves the collodion with great readiness. This will hardly be necessary, as the collodion, even if applied to a part where it were not required, causes at most only slight inconvenience, but not great pain, and is not productive of dangerous results.

— The *British Medical Journal* is responsible for the statement in a late article that there has been only one single outbreak of trichinosis recognized in England, and that was from eating the flesh of a home-bred pig.
